CO₂ EMISSIONS FROM FUEL COMBUSTION H I G H L I G H T S

In the lead-up to the UN climate negotiations in Cancún, the latest information on the level and growth of CO₂ emissions, their source and geographic distribution will be essential to lay the foundation for a global agreement. To provide input to and support for the UN process the IEA is making available for free download the “Highlights” version of *CO₂ Emissions from Fuel Combustion*.

This annual publication contains:

- estimates of CO₂ emissions by country from 1971 to 2008,
- selected indicators such as CO₂/GDP, CO₂/capita, CO₂/TPES and CO₂/kWh,
- CO₂ emissions from international marine and aviation bunkers, and other relevant information.

The sixteenth session of the Conference of the Parties to the Climate Change Convention (COP 16), in conjunction with the sixth meeting of the Parties to the Kyoto Protocol (CMP 6), will be meeting in Cancún from 29 November to 10 December 2010. This volume of “Highlights”, drawn from the full-scale study, was specially designed for delegations and observers of the meeting in Cancún Mexico.

INTERNATIONAL ENERGY AGENCY

The International Energy Agency (IEA), an autonomous agency, was established in November 1974. Its mandate is two-fold: to promote energy security amongst its member countries through collective response to physical disruptions in oil supply and to advise member countries on sound energy policy.

The IEA carries out a comprehensive programme of energy co-operation among 28 advanced economies, each of which is obliged to hold oil stocks equivalent to 90 days of its net imports. The Agency aims to:

- Secure member countries' access to reliable and ample supplies of all forms of energy; in particular, through maintaining effective emergency response capabilities in case of oil supply disruptions.
- Promote sustainable energy policies that spur economic growth and environmental protection in a global context – particularly in terms of reducing greenhouse-gas emissions that contribute to climate change.
- Improve transparency of international markets through collection and analysis of energy data.
- Support global collaboration on energy technology to secure future energy supplies and mitigate their environmental impact, including through improved energy efficiency and development and deployment of low-carbon technologies.
- Find solutions to global energy challenges through engagement and dialogue with non-member countries, industry, international organisations and other stakeholders.

IEA member countries:

Australia

FOREWORD

In the lead-up to the UN climate negotiations in Cancún, the latest information on the level and growth of CO₂ emissions, their source and geographic distribution will be essential to lay the foundation for a global agreement. To provide input to and support for the UN process, the IEA is making available for free download – the “Highlights” version of *CO₂ Emissions from Fuel Combustion*. The PDF publication and an EXCEL file with the tables can be downloaded for free at www.iea.org/co2highlights.

Recent years have witnessed a fundamental change in the way governments approach energy-related environmental issues. Promoting sustainable development and combating climate change have become integral aspects of energy planning, analysis and policy making in many countries, including all IEA member states.

The purpose of this volume is to put our best and most current information in the hands of those who need it, including in particular the participants in the UNFCCC process. The IEA Secretariat is a contributor to the official Intergovernmental Panel on Climate Change (IPCC) methodologies for estimating greenhouse-gas emissions. The IEA’s basic energy balance data are the figures most often cited in the field. For these reasons, we felt it appropriate to publish this information in a comprehensive form.

These data are only for energy-related CO₂, not for any other greenhouse gases. Thus they may differ from countries’ official submissions of emissions inventories to the UNFCCC Secretariat.

However, the full-scale study contains data for CO₂ from non-energy-related sources and gas flaring, and emissions of CH₄, N₂O, HFC, PFC and SF₆. In addition, the full-scale study also includes information on “Key Sources” from fuel combustion, as developed in the *IPCC Good Practice Guidance and Uncertainty Management in National Greenhouse Gas Inventories*.

This report is published under my responsibility as Executive Director of the IEA and does not necessarily reflect the views of IEA member countries.

Nobuo Tanaka
Executive Director

Important cautionary notes

- The estimates of CO₂ emissions from fuel combustion presented in this publication are calculated using the IEA energy balances and the default methods and emission factors from the *Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories*. There are many reasons why **the IEA Secretariat estimates may not be the same as the numbers that a country submits to the UNFCCC**, even if a country has accounted for all of its energy use and correctly applied the *IPCC Guidelines*.
- In this publication, the IEA Secretariat presents CO₂ emissions calculated using both the IPCC Reference Approach and the IPCC Tier 1 Sectoral Approach. In some of the OECD non-member countries, there can be **large differences between the two sets of calculations** due to various problems in some energy data. As a consequence, this can lead to different emission trends between 1990 and 2008 for certain countries. Please see Chapter 3, “IEA emissions estimates” for further details.

Energy data on OECD member and non-member countries are collected by the Energy Statistics Division (ESD) of the IEA Secretariat, headed by Jean-Yves Garnier. Karen Tréanton, with the assistance of Stève Gervais, is responsible for the estimates of CO₂ emissions from fuel combustion. Desktop publishing support was provided by Sharon Burghgraeve.

CO₂ emission estimates from 1960 to 2008 for the Annex II countries and from 1971 to 2008 for all other countries are available on CD-ROM suitable for use on IBM-compatible personal computers. To order,

please see the information provided at the end of this publication.

In addition, a data service is available on the Internet. It includes unlimited access through an annual subscription as well as the possibility to obtain data on a pay-per-view basis. Details are available at www.iea.org.

Enquiries about data or methodology should be addressed to:

Karen Tréanton:

1. 2008 SNAPSHOT OF CO₂ EMISSIONS

Latest developments in 2008 (and beyond)

Two important turning points occurred in 2008: for the first time CO₂ emissions from non-Annex I countries¹ surpassed those of the Annex I countries² and the CO₂ emission levels of the Annex I countries fell below 1990 levels. It should be noted, however, that these reductions mostly occurred in the Annex I EIT countries³ and that 2008 emission levels for the Annex II countries⁴ as a whole were actually 12% above 1990 levels.

Global CO₂ emissions increased by 0.4 Gt CO₂ between 2007 and 2008, which represented a growth rate of 1.5%. However, trends varied greatly: emissions of Annex I countries decreased by more than 2%, whereas emissions of non-Annex I countries increased by almost 6%. Due to these diverging trends, for the first time in 2008, the aggregate emissions of the developing countries were larger than those from the developed countries.

1. In this publication, developing countries refers to non-Annex I Parties to the UNFCCC.

2. The Annex I Parties to the 1992 UN Framework Convention on Climate Change (UNFCCC) are: Australia, Austria, Belarus, Belgium, Bulgaria, Canada, Croatia, Czech Republic, Denmark, Estonia, European Economic Community, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Japan, Latvia, Lichtenstein, Lithuania, Luxembourg, Monaco, the Netherlands, New Zealand, Norway, Poland, Portugal, Romania, Russia, the Slovak Republic, Slovenia, Spain, Sweden, Switzerland, Turkey, Ukraine, United Kingdom and United States. See www.unfccc.int.

3. Annex I EIT includes Belarus, Bulgaria, Croatia, Czech Republic, Slovak Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Russia, Slovenia and Ukraine.

4. Annex II includes those countries in Annex I that are not part of Annex I EIT.

The changes were not equal across fuels, regions and sectors. The increase in emissions for developing countries was primarily due to an increase in coal demand. The reduction in emissions for developed countries was due to decreases in the demand for both coal and oil (Figure 1).

Early indications suggest that CO₂ emissions trends in 2009 will be similar to 2008. Emissions in the developing countries will increase with growing consumption of fossil fuels in some of the larger countries. Emissions in the developed countries will continue to decrease in 2009 (about double the drop in 2008) as a result of the recent financial crisis, the slowdown in economic activity and the price signal received by consumers after the high energy prices observed in 2008.

Figure 1. Global change in CO₂ emissions (2007-2008)

Key point: CO₂ emissions in Annex I countries decreased by more than 2% in 2008, whereas emissions in developing countries rose by almost 6%.

In the medium term, the Annex I CO₂ emissions are expected to rebound when economic conditions pick

up. In its Reference Scenario, the *World Energy Outlook (WEO 2009)*⁵ projects that world CO₂ emissions from fuel combustion will continue to grow unabated, reaching 40.2 Gt CO₂ by 2030. Such an emission-growth trend would be in line with the worst-case scenario presented by the Intergovernmental Panel on Climate Change (IPCC)⁶ in the *Fourth Assessment Report* (2007), which projects a world average temperature increase of between 2.4°C and 6.4°C by 2100.

CO₂ emissions by fuel

In 2008, 43% of CO₂ emissions from fuel combustion were produced from coal, 37% from oil and 20% from gas. Growth of these fuels in 2008 was quite different, reflecting varying trends that are expected to continue in the future.

Between 2007 and 2008, CO₂ emissions from the combustion of coal increased by 3% and represented 12.6 Gt CO₂. Currently, coal is filling much of the growing energy demand of those developing countries, such as China and India, where energy-intensive industrial production is growing rapidly and large coal reserves exist with limited reserves of other energy sources (Figure 2). Without additional measures, the *WEO 2009* projects that emissions from coal will grow from 18.6 Gt CO₂ in 2030. *Energy Technology Perspectives (ETP 2010)* shows that intensified use of coal would substantially increase CO₂ emissions unless there was very widespread deployment of carbon capture and storage.

CO₂ emissions from oil remained constant in 2008, decreasing 0.7% during the year. The decreasing share of oil in total primary energy supply (TPES) as a result of the growth of coal and the penetration of gas limited the increase of CO₂ emissions from oil, which produced 10.8 Gt CO₂ in 2008. The *WEO 2009* projects that emissions from oil will grow to 13.6 Gt CO₂ in 2030.

Emissions of CO₂ from gas in 2008 represented 5.8 Gt CO₂, 2.6% higher than in the previous year. Again, the *WEO 2009* projects emissions from gas will continue to grow, rising to 8.0 Gt CO₂ in 2030.

Figure 2. CO₂ emissions by fuel

Key point: Combustion of coal drove the growth in global emissions between 2007 and 2008.

CO₂ emissions by region

Between 2007 and 2008, CO₂ emission trends varied markedly by region. As mentioned earlier, CO₂ emissions from non-Annex I countries grew by 6% while those of the Annex I countries decreased by 2%, causing the aggregate emissions of the developing countries to overtake those of the developed countries. At the regional level (Figure 3), CO₂ emissions increased significantly in China (8%), the Middle East (7%), other Asia (4%), Latin America (4%) and Latin America (4%).

Figure 3. Change in CO₂ emissions by region (2007-2008)

* China includes Hong-Kong.

Key point: Between 2007 and 2008, CO₂ emissions increased significantly in Asia (including China), the Middle East and Latin America.

5. Unless otherwise specified, projections from the *World Energy Outlook* refer to the Reference Scenario from the 2009 edition.

6. The IPCC was created in 1988 by the World Meteorological Organisation and the United Nations Environment Programme to assess scientific, technical and socio-economic information relevant for the understanding of climate change, its potential impacts, and options for adaptation and mitigation.

On the other hand, between 2007 and 2008, CO₂ emissions decreased by 5% in the Annex II Pacific countries⁷, by 3% in Annex II North American countries⁸ and by 2% in the Annex II European countries⁹. Emissions from the group of countries with economies in transition (Annex I EIT) remained fairly stable.

However, regional differences in contributions to global emissions conceal even larger differences among individual countries (Figure 4).

Two-thirds of world emissions for 2008 originated from just ten countries, with the shares of China and the United States far surpassing those of all others. Combined, these two countries alone produced 12.1 Gt CO₂, about 41% of world CO₂ emissions.

Figure 4. Top 10 emitting countries in 2008

Key point: The top 10 emitting countries account for about two-thirds of the world CO₂ emissions.

CO₂ emissions by sector

Two sectors, electricity and heat generation and transport, produced two-thirds of global CO₂ emissions in 2008 (Figure 5).

Figure 5. World CO₂ emissions by sector in 2008

* Other includes commercial/public services, agriculture/forestry, fishing, energy industries other than electricity and heat generation, and other emissions not specified elsewhere.

Key point: The combined share of electricity and heat generation and transport represented two-thirds of global emissions in 2008.

Generation of electricity and heat was by far the largest producer of CO₂ emissions and was responsible for 41% of the world CO₂ emissions in 2008. Worldwide, this sector relies heavily on coal, the most carbon-intensive of fossil fuels, amplifying its share in global emissions. Countries such as Australia, China, India, Poland and South Africa produce between 69% and 94% of their electricity and heat through the combustion of coal.

Between 2007 and 2008, total CO₂ emissions from the generation of electricity and heat were stable (Figure 6), although the fuel mix changed slightly. CO₂ emissions from gas grew by 3% and from coal remained constant while emissions from oil decreased by 4%. The future development of the emissions intensity of this sector depends strongly on the fuels used to generate the electricity and on the share of non-emitting sources, such as renewables and nuclear.

By 2030, the *WEO 2009* projects that demand for electricity will be almost twice as high as current demand, driven by rapid growth in population and income in developing countries, by the continuing increase in the number of electrical devices used in homes and commercial buildings, and by the growth in electrically driven industrial processes.

Transport, the second-largest sector, represented 22% of global CO₂ emissions in 2008. CO₂ emissions in this sector also remained stable between 2007 and 2008 (Figure 7).

7. Annex II Pacific includes Australia, Japan and New Zealand.

8. Annex II North America includes Canada and the United States.

9. Annex II Europe includes Austria, Belgium, Denmark, Finland, France, Germany, Greece, Iceland, Ireland, Italy, Liechtenstein (not available in this publication), Luxembourg, Monaco (included with France), the Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and the United Kingdom.

Figure 6. CO₂ emissions from electricity and heat generation* in 2007 and 2008

* Refers to main activity producers and autoproducers of electricity and heat.

Key point: CO₂ emissions from electricity and heat generation remained constant between 2007 and 2008, after slightly increasing the previous year.

Figure 7. CO₂ emissions from transport in 2007 and 2008

Key point: CO₂ emissions from transport are dominated by road.

The United States has the highest level of passenger travel per capita in the world (more than 25 000 km per person per year). Until recently, lower fuel prices in the United States contributed to the use of larger vehicles, while in Europe higher fuel prices encouraged improved fuel economy (along with the EU voluntary agreement with manufacturers). As a

result, there is more than a 50% variation in the average fuel consumption of new light-duty vehicles across OECD member countries (*ETP 2010*, p. 262).

Global demand for transport appears unlikely to decrease in the foreseeable future; the *WEO 2009* projects that transport will grow by 45% by 2030. To limit the emissions from this sector, policy makers should first and foremost consider measures to encourage or require improved vehicle efficiency, as the United States has recently done and the European Union is currently doing as a follow-up to the voluntary agreements. Policies that encourage a shift from cars to public transportation and to lower-emission modes of transportation can also help. Finally, policies can encourage a shift to new, preferably low-carbon fuels. These include electricity (*e.g.* electric and plug-in hybrid vehicles), hydrogen (*e.g.* through the introduction of fuel cell vehicles) and greater use of biofuels (*e.g.* as a blend in gasoline and diesel fuel). To avoid a rebound in transport fuel demand, these moves must also be backed up by emissions pricing or fuel excise policies.

These policies would both reduce the environmental impact of transport and help to secure domestic fuel supplies, which are sometimes unsettled by the threat of supply disruptions, whether from natural disasters, accidents or the geopolitics of oil trade. As these policies will ease demand growth, they are also likely to help reduce oil prices below what the prices might otherwise be.

Coupling emissions with socio-economic indicators¹⁰

Indicators such as those briefly discussed in this section strongly reflect energy constraints and choices made to supply the economic activities of each country. They also reflect the sectors that predominate in different countries' economies.

In 2008, the largest five emitters (China, the United States, the Russian Federation, India and Japan) comprised 45% of the total population and together produced 55% of the global CO₂ emissions and 50% of the world GDP. However, the relative shares of these five countries for all three variables were very diverse.

10. No single indicator can provide a complete picture of a country's CO₂ emissions performance or its relative capacity to reduce emissions. The indicators discussed here provide an indication of performance but are certainly incomplete.

In the United States, the large share of global emissions is associated with a commensurate share of economic output (GDP), the largest in the world. Japan, with a GDP more than double that of the Russian Federation, emits 28% less than the Russian Federation.

Although climate and other variables also affect energy use, relatively high values of emissions per GDP indicate a potential for decoupling CO₂ emissions from economic growth. Possible improvements can derive from fuel switching away from carbon-intensive sources or from energy efficiency at all stages of the energy supply chain (from fuel extraction to energy end-use).¹¹ Among the five largest emitters of CO₂ in 2008, China, the Russian Federation and the United States have significantly reduced their CO₂ emissions per unit of GDP between 1990 and 2008 (Figure 8). The other two countries, India and Japan, already had much lower emissions per GDP.

Figure 8. Trends in CO₂ emission intensities for the top 5 emitting countries*

* Size of circle represents total CO₂ emissions from the country in that year.

Key point: China, the Russian Federation and the United States have all made significant improvements in the amount of CO₂ emissions per unit of GDP they emit.

Worldwide, the highest levels of emissions per GDP are observed for the oil and gas exporting region of the Middle East, for the relatively energy-intensive EITs and for China (Figure 9).

Figure 9. CO₂ emissions per GDP* by major world regions in 2008

* GDP in 2000 USD, using purchasing power parities.

** China includes Hong Kong.

Key point: Emission intensities in economic terms vary greatly around the world.

As compared to emissions per unit of GDP, the range of per capita emission levels across the world is even larger, highlighting wide divergences in the way different countries and regions use energy.

In 2008, the United States alone generated 19% of world CO₂ emissions, despite a population of less than 5% of the global total. Conversely, China contributed a comparable share of world emissions (22%) while accounting for 20% of the world population. India, with 17% of world population, contributed less than 5% of the CO₂ emissions. Among the five largest emitters, the levels of per capita emissions were very diverse, ranging from 1 t of CO₂ per capita for India and 5 t for China to 18 t for the United States.

Industrialised countries emit far larger amounts of CO₂ per capita than the world average (Figure 10). However, some rapidly expanding economies are significantly increasing their emissions per capita. For example, between 1990 and 2008, among the top 5 emitting countries, China more than doubled its per capita emissions and India increased them by almost 80%. Clearly, these two countries contributed much to the 10% increase of global per capita emissions over the period. Conversely, both the Russian Federation and the United States decreased their per capita emissions significantly over the same period.

11. The IEA's Policies and Measures Databases offer access to information on energy-related policies and measures taken or planned to reduce greenhouse-gas emissions, improve energy efficiency and support renewable energy development and deployment. The online databases can be consulted at: www.iea.org/textbase/pm/index.html.

Figure 10. CO₂ emissions per capita by major world regions in 2008T CO₂ per capita

* China includes Hong Kong.

Key point: Emissions per capita vary even more widely across world regions than GDP per capita.

Developing a low-carbon world

Until recently, industrialised countries have emitted the large majority of anthropogenic greenhouse gases. However shares of developing countries are rising very rapidly and are projected to continue to do so. To shift towards a low-carbon world, mitigation measures now taking shape within industrialised countries will need to be accelerated, and complemented by comprehensive efforts worldwide.

Complementing various national policies and measures, the Kyoto Protocol of the UNFCCC is by far the most comprehensive multinational effort to mitigate climate change, both politically and geographically. Having entered into force in February 2005, the Protocol commits industrialised countries (as a group) to curb domestic emissions by about 5% relative to 1990 by the 2008-12 first commitment period. The Protocol also creates “flexible mechanisms” by which industrialised countries can

transfer emission allowances among themselves and earn emission credits from emissions reduction projects in participating developing countries and EIT countries.

Despite its extensive coverage (192 countries), the Protocol is limited in its potential to address global emissions since not all major emitters are included in reduction commitments. The United States remains outside of its jurisdiction and though most developing countries (*i.e.* non-Annex I countries) have signed the Protocol, they do not face emissions targets. The Kyoto Protocol implies action on less than one-third of global CO₂ emissions as measured in 2008 (Table 1).

The Protocol has made carbon a tradable commodity, and has been a key driver for the development of emissions trading schemes as detailed in the following section.

Emissions trading schemes

Emissions trading schemes (ETS) are developing or being proposed in several regions and countries around the world. While some are operational (EU ETS, New Zealand, Norway, Tokyo, Switzerland, the Regional Greenhouse Gas Initiative in the United States, Alberta, and New South Wales Australia) or intend to begin soon (the Western Climate Initiative among US states and Canadian provinces), other jurisdictions are still evaluating options (Japan, Korea, Brazil, China, Canada) or considering whether to proceed with existing well-developed proposals (Australia, United States).

Given the significant uncertainties surrounding future international climate commitments, policy makers have allowed flexibility in changing design options over the longer term. Indeed, lessons from the first years of existing schemes are helping the elaboration of others (Reinaud and Philibert, 2007).

In the European Union, the largest scheme in operation is the EU ETS, which covers emitters in the energy and industrial sectors (aviation will be added from 2012). Norway’s ETS is fully linked to the EU system. The lessons from its first two phases have helped to shape the scheme’s post-2012 design (Ellerman *et al.*, 2010).

Slovenia	12.5	16.7	33.8%	-8%					
Ukraine	687.9	309.6	-55.0%	0%					

(1) The targets apply to a basket of six greenhouse gases and allow sinks and international credits to be used for compliance with the target. The overall EU-15 target under the Protocol is 8%, but the member countries have agreed on a burden-sharing arrangement as listed. Because of lack of data and information on base years and gases, an overall "Kyoto target" cannot be precisely calculated for total Kyoto Parties: estimates applying the targets to IEA energy data suggest the target is equivalent to about 4.7% on an aggregate basis for CO₂ emissions from fuel combustion.

(2) Emissions from Monaco are included with France.

(3) Composition of regions differs from elsewhere in this publication to take into account countries that are not Kyoto Parties.

(4) The Kyoto target is calculated as percentage of the 1990 CO₂ emissions from fuel combustion only, therefore it does not represent the total target for the six-gas basket. This assumes that the reduction targets are spread equally across all gases.

Key point: Existing climate goals have not always led to reductions in CO₂ emissions from fuel combustion.

In December 2008, the European Council and the European Parliament endorsed an agreement on the climate change and energy package which implements a political commitment by the European Union to reduce its greenhouse-gas emissions by 20% by 2020 compared to 1990 levels.¹² The EU ETS will play a key role in achieving this target, as the 2020 emissions cap for ETS installations is 21% below the actual level of 2005 emissions,¹³ or 34% below if the overall target moves to a 30% reduction. There will be a significant increase in the proportion of allowances auctioned rather than allocated for free, including full auctioning (in general) for the power generation sector. Continued use of credits from the Kyoto Protocol flexible mechanisms Clean Development Mechanism (CDM) and Joint Implementation (JI) will be allowed, with both quantitative and qualitative restrictions.

In New Zealand, a comprehensive economy-wide emission trading scheme (NZ ETS) is being progressively introduced, starting with the forestry sector in January 2008. The energy, transport and industrial sectors are included from July 2010, and waste and agricultural emissions enter by 2015. There is a transition phase from 2010 to 2012 with a capped price and partial obligations. The scheme is fully linked to the international Kyoto market, and allows unlimited use of Kyoto Protocol project and forestry credits. No emissions cap is specified: linking to the international market is intended rather to ensure that an appropriate carbon price is set in the New Zealand economy.

Several other ETS schemes are operating, including in countries that are not Parties to the Kyoto Protocol. In the United States, the first regional scheme (the Regional Greenhouse Gas Initiative covering the electricity sector in the northeastern states) began on 1 January 2009. Small schemes are also in place in New South Wales Australia (covering the power sector), Tokyo (covering commercial sites) and Alberta (covering large emitters). Switzerland's ETS allows companies to manage their emissions through trading instead of facing the country's carbon tax.

The Western Climate Initiative is a collective emissions trading system agreed between 11 US states and

Canadian provinces. Trading is scheduled to begin in 2012, and a smaller group of five participants (California, New Mexico, British Columbia, Ontario and Quebec) currently intend to begin trading at that time. The programme is designed to reduce emissions to 15% below 2005 levels by 2020, with allocations starting at a best-estimate of actual 2012 emissions. The scheme will have a broad scope once fully phased in, covering up to 90% of economy-wide emissions, although individual states have discretion over which sectors will be included.

Other detailed proposals for ETS have been developed in Australia and the United States, but in both cases legislation to enact the schemes failed to pass.

In Australia, the so-called Carbon Pollution Reduction Scheme (CPRS) included broad coverage of greenhouse-gas emissions and sectors, covering around 75% of Australian greenhouse-gas emissions, a mix of direct and upstream point of obligation, and assistance to help households and business adjust. Australian climate policy is now to be reviewed following parliamentary elections.

In the United States, the House of Representatives passed the American Clean Energy and Security Act (ACES) in June 2009, a comprehensive climate change and energy package. The bill includes a cap-and-trade programme covering 85% of US greenhouse-gas emissions, including power, industry, transport, commercial and residential sectors. The targets are set against 2005 emission levels, at 3% reduction by 2012, 17% by 2020, 42% by 2030 and 83% by 2050. However similar legislation failed to achieve support in the Senate, and this bill will not proceed in its current form.

A number of other domestic trading schemes are also under consideration.

The Canadian government intends to introduce domestic emissions trading as part of a market-based approach to reducing emissions of greenhouse gases, and has developed a domestic offsets programme as a step towards this. Canada will seek to align the design of its scheme with future US markets.

Japan's government intends to implement a mandatory emissions trading scheme to help meet its goal of a 25% reduction in greenhouse gases by 2020. Design options being considered range from economy-wide to power-sector-only trading, and emissions obligations could be absolute caps or output-based. The infrastructure for emissions trading is already established in Japan, with an active voluntary trading scheme

12. A 30% reduction target is proposed if other Parties were to take equally ambitious mitigation objectives.

13. Annual cap: 1 974 Mt in 2013, falling in linear fashion to 1 720 Mt by 2020; average annual cap over 2013-20: 1 846 Mt (compared to an annual cap of 2 083 Mt in phase 2). If the overall target moves to a 30% reduction, the 2020 ETS cap will be reduced to 34% below 2005 levels.

established in 2005 (the Keidanren Voluntary Action Plan), and a voluntary experimental emissions trading scheme launched in 2008.

The Korean government intends to submit legislation in 2010 to establish an emissions trading scheme, to assist in delivering Korea's target of a 30% improvement on business-as-usual (BAU) emissions by 2020. Details are still being developed, but it will reportedly cover around 600 large companies responsible for 70% of Korea's emissions, starting around 2012.

Brazil is also reportedly considering the introduction of a domestic emissions trading scheme, to help deliver its target of reducing emissions by up to 38.9% by 2020. The role of a carbon market is being studied for reducing emissions in the power, transport, agriculture and industrial sectors. Further details may be available in 2010.

China intends to set emissions targets for selected areas as part of its 12th five-year plan (2011 to 2015), with emissions trading a key tool being considered for delivery of these targets.

Steps for future action

Held in late 2005, the first Meeting of the Parties to the Kyoto Protocol (COP/MOP1) witnessed the official opening of talks on post-2012 climate change policy. The Bali Road Map adopted at COP/MOP3 in Bali in 2007 established a two-track process, *i.e.* both for the Convention and Kyoto Protocol strands, aiming at the identification of a post-2012 global climate regime to be adopted by COP15 and COP/MOP5 in Copenhagen in 2009. In Bali, Parties organised two official fora: the Ad Hoc Working Group on the Kyoto Protocol (AWG-KP) and the Ad Hoc Working Group on Long-term Co-operative Action (AWG-LCA).

The AWG-KP focuses on the design of post-2012 commitments for Annex I Parties under the Protocol. Ideally, it would also provide some certainty to carbon-constrained investments in infrastructure and to the carbon market itself. However, the AWG has no mandate to encourage participation from non-Annex I Parties or from non-participating Annex I Parties.

By contrast, the broader AWG-LCA was designed to enable full and sustained implementation of the UN Framework Convention on Climate Change by all Parties, up to and beyond 2012, through long-term co-operative action. While the Bali Action Plan, adopted under the Convention track, did not introduce binding commitments to reduce greenhouse-gas emissions, it

included the request for developing countries to contribute to the mitigation of global warming in the context of sustainable development. In addition, the plan envisaged enhanced actions on adaptation, technology development and on the provision of financial resources, as well as measures against deforestation. The Bali Action Plan introduced a focus on mitigation actions by all Parties and the provision of financial resources by developed countries that are "measurable, reportable and verifiable", now central to the establishment of a post-2012 framework for climate action.

COP15 and COP/MOP5 in Copenhagen did not see the identification of a post-2012 global climate regime, and the mandate of the two AWGs was extended for another year. In an unprecedented move, heads of states and high-level representatives negotiated the Copenhagen Accord, stating the goal of limiting global temperature increase to 2°C above pre-industrial levels, outlining commitments for the provision of financial resources, and sketching a framework for monitoring and reviewing mitigation actions and commitments. Annex I Parties submitted quantified economy-wide greenhouse-gas targets to 2020 as part of the accord, and several non-Annex I countries also listed mitigation actions, or sectoral or economy-wide greenhouse-gas targets. While the Copenhagen Accord was not adopted as a COP decision, 138 Parties have expressed their intention to be listed as agreeing to the Accord as of September 2010.

The challenge of post-2012 discussions is the need to engage developing countries with approaches, possibly including the carbon market, which suit their capacity and their legitimate aspiration for economic and social development. The Asia Pacific Partnership for Clean Development and Climate (APP or AP7), the G8 2005 Gleneagles Plan of Action, and the Major Economies Forum on Energy and Climate (MEF) and Clean Energy Ministerial processes seek to involve developed and developing nations in common measures to address climate change. Other international fora gathering both developed and developing countries have emerged to further mitigation efforts in specific areas, such as the International Renewable Energy Agency (IRENA), and the International Partnership for Energy Efficiency Co-operation (IPEEC).

The AP7, which groups Australia, Canada, China, India, Japan, Korea and the United States, focuses on the emissions of specific sectors (iron and steel, cement, aluminium, mining, buildings and appliances) and the methods of clean fossil energy use, renewable

energy generation and more efficient power generation and transmission.

Canada, France, Germany, Italy, Japan, the Russian Federation, the United Kingdom and the United States launched the July 2005 G8 Gleneagles Plan of Action to, in part, promote clean energy and sustainable development while mitigating climate change. The IEA was tasked under the Plan of Action to develop concrete recommendations to help the G8 achieve its clean energy objectives. Additionally, the G8 sought to engage South Africa, India, Brazil, China and Mexico in an official dialogue to address climate change, clean energy, and sustainable development worldwide. This commitment by the G8 was reiterated at all subsequent summits.

Launched in March 2009, the MEF has facilitated candid dialogue among 17 major economies, both developed and developing, to help achieve a successful outcome in UN climate negotiations. It also supports concrete initiatives and joint ventures aimed at increasing the supply of clean energy while reducing greenhouse-gas emissions. At the G8 summit in L'Aquila, Italy on 9 July 2009, the 17 heads of the MEF countries set a clear goal for international climate policy: the increase in global climate temperature above pre-industrial levels ought not to exceed 2°C. The G20 summits have also served as a forum to advance climate change and clean energy discussions, including a commitment to rationalising and phasing out inefficient fossil fuel subsidies over the medium term.

In all these efforts, timely and accurate CO₂ and other greenhouse-gas statistics will prove central to ascertain compliance to international agreements and to inform policy makers and carbon market participants. The ability of countries to monitor and review emissions from their sources is essential in their engagement towards national and global greenhouse-gas mitigation.

2. REGIONAL ASPECTS OF THE ENERGY-CLIMATE CHALLENGE

A growing body of evidence establishes the links between climate change and the CO₂ emissions that arise from energy production and consumption. This chapter provides background on the link between energy use and climate change and then examines how growing demand in some rapidly expanding economies, all of which are in non-OECD regions, will dramatically change future emissions trends. It closes with a call for all countries (and not just the industrialised countries) to address this increasingly urgent global issue.

Understanding energy and climate change

In its *Fourth Assessment Report*¹⁴, the IPCC concluded: “Most of the observed increase in global average temperatures since the mid-20th century is *very likely* due to the observed increase in anthropogenic greenhouse-gas concentrations”. The language “very likely” has been upgraded from the “likely” that was referred to six years earlier in the *Third Assessment Report*, thus confirming the broad acceptance by scientists of the link between greenhouse-gas emissions and global climate change. Energy production and use have various environmental implications: since energy represents about 65% of global anthropogenic greenhouse-gas emissions, reducing emissions must

necessarily start with actions geared to reduce emissions from fuel combustion.

Greenhouse gases and global warming

The increased concentrations of key greenhouse gases are a direct consequence of human activities. Since anthropogenic greenhouse gases accumulate in the atmosphere, they produce net warming by strengthening the natural “greenhouse effect”.

Carbon dioxide (CO₂) concentrations in the atmosphere have been increasing over the past century compared to the rather steady level of the pre-industrial era (about 280 parts per million in volume, or ppmv). The 2005 concentration of CO₂ (379 ppmv) was about 35% higher than in the mid-1800s, with the fastest growth occurring in the last ten years (1.9 ppmv/year in the period 1995-2005). Significant increases have also occurred in levels of methane (CH₄) and nitrous oxide (N₂O).

Some impacts of the increased greenhouse-gas concentrations may be slow to become apparent since stability is an inherent characteristic of the interacting climate, ecological and socio-economic systems. Even after stabilisation of the atmospheric concentration of CO₂, anthropogenic warming and sea level rise would continue for centuries due to the time scales associated with climate processes and feedbacks. Some changes in the climate system would be irreversible in the course of a human lifespan.

Given the long lifetime of CO₂ in the atmosphere, stabilising concentrations of greenhouse gases at any level would require large reductions of global CO₂ emissions from current levels. The lower the chosen level for stabilisation, the sooner the decline in global CO₂ emissions would need to begin, or the deeper the emission reduction would need to be on the longer term.

14. IPCC *Fourth Assessment Report – Climate Change 2007*, available at www.ipcc.ch. In the summary for policy makers, the following terms have been used to indicate the assessed likelihood, using expert judgement, of an outcome or a result: *Virtually certain* > 99% probability of occurrence, *Extremely likely* > 95%, *Very likely* > 90%, *Likely* > 66%, *More likely than not* > 50%, *Unlikely* < 33%, *Very unlikely* < 10%, *Extremely unlikely* < 5%.

The UNFCCC creates a structure for intergovernmental efforts to tackle the challenge posed by climate change. The Convention's ultimate objective is to stabilise greenhouse-gas concentrations in the atmosphere at a level that would prevent dangerous anthropogenic interference with the climate system. This would require significant reductions in global greenhouse-gas emissions.

Energy use and greenhouse gases

Among the many human activities that produce greenhouse gases, the use of energy represents by far the largest source of emissions. Energy accounts for over 80% of the anthropogenic greenhouse gases in Annex I countries, with emissions resulting from the production, transformation, handling and consumption of all kinds of energy commodities (Figure 11). Smaller shares correspond to agriculture, producing mainly CH₄ and N₂O from domestic livestock and rice cultivation, and to industrial processes not related to energy, producing mainly fluorinated gases and N₂O.

Figure 11. Shares of anthropogenic greenhouse-gas emissions in Annex I countries, 2008*

* Based on Annex I data for 2008; without Land Use, Land-Use Change and Forestry, and with Solvent Use included in Industrial Processes.

Source: UNFCCC.

Key point: Accounting for the largest share of global greenhouse-gas emissions, energy emissions are predominantly CO₂.

Greenhouse-gas emissions from the energy sector are dominated by the direct combustion of fuels.¹⁵ A by-

product of fuel combustion, CO₂ results from the oxidation of carbon in fuels.

CO₂ from energy represents about 83% of the anthropogenic greenhouse-gas emissions for the Annex I countries and about 65% of global emissions. This percentage varies greatly by country, due to diverse national energy structures.

Worldwide economic stability and development require energy. Global total primary energy supply (TPES) doubled between 1971 and 2008, mainly relying on fossil fuels (Figure 12).

Figure 12. World primary energy supply*

Gt of oil equivalent

* World primary energy supply includes international bunkers.

Key point: Fossil fuels still account for most of the world energy supply.

Despite the growth of non-fossil energy (such as nuclear and hydropower) considered as non-emitting,¹⁶ fossil fuels have maintained their shares of the world energy supply relatively unchanged over the course of the past 35 years. In 2008, fossil sources accounted for 81% of the global TPES.

Though coal represented only one-quarter of the world TPES in 2008, it accounted for 43% of the global CO₂ emissions due to its heavy carbon content per unit of energy released (Figure 13). As compared to gas, coal is on average nearly twice as emission intensive.¹⁷

15. Energy includes emissions from "fuel combustion" (the large majority) and "fugitive emissions", which are intentional or unintentional releases of gases resulting from production, processes, transmission, storage and use of fuels (e.g. CH₄ emissions from coal mining or oil and gas systems).

16. Excluding the life cycle of all non-emitting sources and excluding combustion of biomass (considered as non-emitting CO₂, based on the assumption that the released carbon will be reabsorbed by biomass regrowth, under balanced conditions).

17. IPCC default carbon emission factors from the 1996 IPCC Guidelines: 15.3 t C/TJ for gas, 16.8 to 27.5 t C/TJ for oil products, 25.8 to 29.1 t C/TJ for primary coal products.

Figure 13. World primary energy supply and CO₂ emissions: Shares by fuel in 2008

Percent share

* Other includes nuclear, hydro, geothermal, solar, tide, wind, combustible renewables and waste.

Key point: Coal generates about twice the CO₂ emissions of gas, while having a comparable share in the world energy supply.

Growing world energy demand from fossil fuels plays a key role in the upward trend in CO₂ emissions (Figure 14). Since the Industrial Revolution, annual CO₂ emissions from fuel combustion dramatically increased from near zero to 29 Gt CO₂ in 2008.

Figure 14. Trend in CO₂ emissions from fossil fuel combustion

Source: Carbon Dioxide Information Analysis Center, Oak Ridge National Laboratory, US Department of Energy, Oak Ridge, Tenn., United States.

Key point: Since 1870, CO₂ emissions from fuel combustion have risen exponentially.

The link between climate change and energy is a part of the larger challenge of sustainable development. The socio-economic and technological characteristics of development paths will strongly affect emissions, the rate and magnitude of climate change, climate change impacts, the capability to adapt and the capacity to mitigate the emissions themselves.

BRICS countries altering regional balance

One of the most important recent developments in the world economy is the increasing economic integration of large non-OECD countries, in particular Brazil, the Russian Federation, India, China and South Africa, the so-called BRICS countries. Already, the BRICS represent over one-fourth of world GDP, up from 18% in 1990. In 2008, these five countries represented 31% of global energy use and 35% of CO₂ emissions from fuel combustion (Figure 15). These shares are likely to rise further in coming years if the strong economic performance currently occurring in most of these countries continues, as many commentators expect. In fact, China, the Russian Federation and India are already three of the four countries that emit the most CO₂ emissions in absolute terms.¹⁸

Figure 15. The growing importance of the BRICS countries

Key point: With the exception of the Russian Federation, the BRICS countries represent a growing share of CO₂ emissions in the world.

This brief discussion focuses on the BRICS countries, of which only the Russian Federation is a member of Annex I Parties to the UNFCCC. Each of these countries has very different endemic resources, energy supply constraints and sectoral consumption patterns. Consequently, the issues relating to CO₂ emissions facing these five countries are quite different.

18. The largest emitter is the United States.

Brazil

Brazil is the third-largest emitter of total greenhouse gases in the world, with the particularity that the country's energy system has a relatively minor impact on greenhouse-gas emissions (only 15%). The bulk of Brazilian greenhouse-gas emissions (85%) comes instead from agriculture, land-use and forestry activities, mainly through the expansion of agricultural frontiers in the Amazon region.

Compared to the Russian Federation, China and India, CO₂ emissions from fuel combustion in Brazil are small, representing only 1.2% of global CO₂ emissions from fuel combustion. Brazil's energy matrix is one of the cleanest in the world with renewables accounting for 44% of TPES. Brazil is also one of the world's largest producers of hydropower. Within the energy sector, the sub-sectors that contribute the most to total greenhouse-gas emissions – transport (41% in 2008) and industry (30%) – are those likely to grow the most over the next years (Figure 16).

Figure 16. Brazil: CO₂ emissions by sector

Key point: *The transport sector produces the largest share of CO₂ emissions from fuel combustion in Brazil.*

Electricity generation in Brazil relies heavily on hydropower (Figure 17). Over the last three decades, the number of major dams has grown steadily and hydropower accounted for 80% of total electricity generation in 2008. Many of Brazil's hydropower generating facilities are located far away from the main demand centres, resulting in high transmission and distribution losses. Droughts in recent years have led to a wider diversification in the electricity production mix, increasing the use of gas.

Figure 17. Brazil: Electricity generation by fuel

Key point: *Brazilian electricity generation draws heavily on hydropower.*

In 2009, the government announced plans to build two new large hydroelectric plants. As a result, there are currently 22 GW of hydropower capacity already contracted and under construction (including the 11.2 GW of the Belo Monte) plus 3.9 GW of small hydro plants. However, unclear regulation of the power sector remains a source of concern. Environmental issues have also delayed some of the large hydropower projects.

In 2007, amid concerns about the risk of power-supply shortages beyond 2012 unless Brazil builds new capacity, the Brazilian government announced the development of five new nuclear power plants. The government's 2030 National Energy Plan anticipates 5.3 GW of additional installed generation capacity from new nuclear plants (Angra 3 and four other plants) by 2030. Moreover, electricity produced from CHP plants, mainly from sugarcane bagasse, is to make up 11.4% of the country's electricity supply by 2030.

Biofuels supply a comparatively significant share of the energy consumed for road transport (Figure 18). As such, Brazilian transport has a relatively low CO₂ emissions intensity.¹⁹ CO₂ emissions per unit of fuel consumed in road traffic are 10% lower than the world average (2.6 versus 2.9 t CO₂ per toe).

19. See box on "Using biofuels to reduce emissions" for a more complete discussion on the advantages and limitations of using biofuels to replace oil. Note: CO₂ emissions intensity considers the tank-to-wheel emissions and assumes that the CO₂ emissions derived from the combustion of biomass are zero.

Using biofuels to reduce emissions

Compatible with many conventional engines and blendable with current transport fuels, biofuels have the potential to reduce greenhouse-gas emissions and to contribute to energy security by diversifying supply sources for transport. However, the economic, environmental and social benefits of the current generation of biofuels vary enormously.

Despite important uncertainties about their efficacy in reducing greenhouse-gas emissions, biofuels can be compared on the basis of their well-to-wheel* performance with respect to conventional fossil fuels. When ethanol is derived from corn, the well-to-wheel greenhouse-gas reduction with respect to conventional gasoline is typically in the range of 10% to 30%. The reduction is much higher for sugarcane-based ethanol from Brazil, reaching an estimated 90%. Similarly, oilseed-derived biodiesel typically leads to greenhouse-gas reductions, on a well-to-wheel basis, of 40% to 60% when compared to conventional petroleum diesel.

However, these comparisons do not take into account the possibility that changes in land use from starting biofuels production can result in one-time releases of CO₂ that could be quite large; more research is needed on the impacts of both direct and indirect land-use change and how to minimise adverse impacts.

New and emerging biofuels technologies, which can use as feedstock cellulosic residues and non-food crops such as trees and perennial grasses, have the potential to dramatically expand the scope for production of very low-carbon biofuel. However these biofuel technologies are not yet commercially operational at full scale. The most mature of these technologies are still at the demonstration stage.

For both current and second-generation biofuels, production cost is the main barrier to their larger penetration in the transport fuel mix. Without subsidies, only ethanol from sugarcane produced in Brazil has been competitive with petroleum fuels, although this may change with the higher oil prices occurring recently. The cost barrier is such that market introduction of biofuels has typically required substantial regulatory intervention and governmental support.

Currently, several countries have mandated or promoted biofuel blending standards to displace oil in domestic transport supply. In Brazil, gasoline contains 20% to 25% ethanol. Furthermore, 84% of the cars produced in Brazil in 2009 can run on either 100% ethanol or on the gasoline/ethanol blend. With recent high oil prices, most drivers are choosing to operate these vehicles mainly on ethanol. In 2006, the United States introduced mandatory standards and these were extended in 2007 under the EISA law. Blending requirements will reach 12.9 billion gallons in 2010 and 36 billion gallons by 2022 (of which more than half will be required to be advanced biofuels and about one-third cellulosic).**

Several years ago, the European Union introduced a target for biofuel use equivalent to 2% of the market share of motor fuel by 2005 (although it was not reached) and 5.75% by the end of 2010. The target for renewable energy sources in transport for 2020 is now set at 10%. The current legislation also requires "sustainability criteria" favouring biofuels derived from waste, residues, non-food cellulosic material and lignocellulosic material in order to prevent mass investment in biofuels when their use may potentially be harmful to the environment. Australia (New South Wales and Queensland) and Canada are also mandating the use of biofuels, as are a number of non-OECD countries.

For the future, it is crucial that policies foster innovation and support only the most sustainable biofuels, through a continuous monitoring and assessment of their effectiveness in reducing greenhouse-gas emissions and in providing benefits for rural workers. Suitable land availability and potential influence of biofuel production on global food prices also need to be carefully monitored, taking into account all global food, fibre and energy needs for the growing world population out to 2100. However, barriers to the commercial viability of biofuels shrink as technologies evolve and as prices of conventional fossil fuels remain high. Moreover, if well managed and co-ordinated with investments in infrastructures and agriculture, biofuels can provide an opportunity for increasing land productivity and creating economic development, particularly in rural areas.

* Well-to-wheel in life cycle analysis refers to the total emissions from the production stage to the consumption stage of the product.

** Cellulose is an organic compound with the formula C₆H₁₀O₅ and is the structural component of the primary cell wall of green plants. Lignocellulosic biomass refers to plant biomass that is composed of cellulose, hemicellulose and lignin.

Brazil is the world's largest exporter and consumer of fuel ethanol from sugarcane.²⁰ In 2009, Brazil produced 450 000 bbl/d of ethanol, up from 410 000 bbl/d in 2008. Currently, cars that can run on either 100% ethanol or a gasoline-anhydrous ethanol

blend represent 84% of the new cars purchased in Brazil (an estimated 2.2 million in 2009) and cost the same as cars that can only run on conventional fuel.

Brazil's profile as an energy producer will be transformed in the medium term, following the discovery in November 2007 of a major deepwater oilfield in the Santos Basin. Brazil's oil and gas reserves are currently estimated at 14 billion barrels.

20. In 2005, the United States displaced Brazil as the largest ethanol producer, although mainly derived from corn and not sugarcane.

Figure 18: Share of biofuels energy in road transport (2008)

Key point: Brazil's relative consumption of biofuels far outstrips that of any other country.

Russian Federation

The Russian Federation is the only one of the BRICS countries where CO₂ emissions fell between 1990 and 2008, with a 27% drop over the period (Figure 19). The economic downturn after the break-up of the Former Soviet Union caused emissions to fall by 34% between 1990 and 1998. CO₂ emissions grew in 1999 and 2000 (3% a year) due to the Russian Federation's strong economic recovery, stimulated by the increase in world energy prices. CO₂ emissions remained fairly constant for the next five years. After a 4% increase in 2006, the CO₂ emissions were stable in 2007 and increased by 1% in 2008. The *WEO 2009* Reference Scenario projects that the Russian Federation CO₂ emissions will continue to increase steadily, and in 2030 will represent around 90% of the estimated 1990 level. The *WEO 2009* bases its GDP growth rate assumptions on IMF data, which is more conservative than the GDP growth outlook of the Russian government. That being said, Russian assumptions for energy efficiency gains are more bullish than *WEO 2009*, such that the end result in terms of CO₂ emissions is similar. The Russian Energy Strategy projects overall greenhouse-gas emissions in 2030 to be around 100-105% of the estimated 1990 level.

CO₂ emissions from fuel combustion in the Russian Federation have stabilised following the collapse of the Former Soviet Union. However, other sources of greenhouse gases (in particular CH₄ emissions from leaks in the oil and gas transmission/distribution system and CO₂ emissions from flaring of associated gas) represent an important share of the Russian greenhouse-gas emissions. To effectively reduce greenhouse-gas emissions from energy, these two problems would also need to be addressed (IEA, 2006a).

Figure 19. Russian Federation: CO₂ emissions by sector

Key point: CO₂ emissions in the Russian Federation have remained fairly constant over the last ten years.

In 2008, the electricity and heat generation sector represented 55% of Russian CO₂ emissions, compared to a global average of 41%. Within this sector, 48% of the electricity was generated by natural gas, 19% by coal and only 2% by oil (Figure 20).

Figure 20. Russian Federation: Electricity generation by fuel

Key point: A large portion of the Russian Federation's electricity and heat generation comes from non-emitting (nuclear and hydro) or low-emitting (natural gas) sources.

The Russian government enacted a decree in January 2009 that sets targets to increase the share of electricity generated by renewable energy sources to raise the renewable share in TPES from less than 1% to more than 4.5% by 2020. This decree could go a long way to get the Russian Federation more in line with the global average. However, to stimulate the utilisation of renewables

energy sources including wind, biomass, solar and re-covered methane from coal mines (coalmine methane), a range of supporting regulations will be needed, amplifying this important framework legislation.

Of the BRICS countries, in 2008, the Russian Federation had the highest CO₂ emissions per capita (11.2 t CO₂), which put it close to the average of OECD member countries (10.6 t CO₂). In terms of CO₂/GDP, the Russian Federation's economy remains CO₂ intensive with 1.0 kg CO₂ per unit of GDP, more than 2.5 times higher than the OECD average. Canada, whose geography and natural resources are comparable to those of the Russian Federation, has a carbon intensity of 0.5 kg CO₂/USD – half of the Russian Federation's level. However, IEA statistics show a reduction of the Russian Federation's energy intensity of GDP of about 5% per year since 1998. It is not clear how much this can be attributed to energy efficiency improvements as opposed to the dramatic increase in GDP due to the Russian Federation's much higher export earnings from oil and gas.

India

India emits nearly 5% of global CO₂ emissions, and emissions continue to grow. CO₂ emissions have more than doubled between 1990 and 2008. The *WEO 2009* Reference Scenario projects that CO₂ emissions in India will increase by more than 2.5 times by 2030 from 2008. A large share of these emissions is produced by the electricity and heat sector, which represented 56% of CO₂ in 2008, up from 42% in 1990. The transport sector, which was only 9% of CO₂ emissions in 2008, is growing relatively slowly compared to other sectors of the economy (Figure 21).

Figure 21. India: CO₂ emissions by sector

Key point: The bulk of CO₂ emissions in India comes from the electricity and heat generation sector and its share is continuing to grow.

In 2008, 69% of electricity in India came from coal, another 10% from natural gas and 4% from oil (Figure 22). The share of fossil fuels in the generation mix grew from 73% in 1990 to 85% in 2002. The share of fossil fuels has declined steadily since then, falling to 81% in 2007, although increasing back up to 83% in 2008. Although electricity produced from hydro has actually risen during this period, the share fell from 25% in 1990 to 14% in 2008. India is promoting the addition of other renewable power sources into its generation mix and had an installed capacity of 17 GW of renewable energy sources on 30 June 2010. Under its National Action Plan on Climate Change, India plans to install 20 GW of solar power by 2020. With an installed wind capacity of 12 GW in June 2010,²¹ India has the world's fifth-largest installed capacity of wind power.

Figure 22. India: Electricity generation by fuel

Key point: About two-thirds of India's electricity comes from coal.

Of the BRICS countries, India has the lowest CO₂ emissions per capita (1.3 t CO₂ in 2008), about one-fourth that of the world average. However, due to the recent large increases in emissions, the Indian ratio is more than 1.5 times that of its ratio in 1990 and will continue to grow. India's per capita emissions in 2030 will, however, still be well below those in the OECD member countries today.

In terms of CO₂/GDP, India has continuously improved the efficiency of its economy and reduced the CO₂ emissions per unit of GDP by 21% between 1990 and 2008. India aims to further reduce emissions intensity of GDP by 20-25% by 2020 compared with the 2005 level.²²

22. As per its stated goal in association with the Copenhagen Accord.

China

With more than six billion tonnes of CO₂ in 2008 (22% of global emissions), Chinese emissions surpass by far those of the other BRICS countries – in fact, China overtook the United States in 2007 as the world's largest annual emitter of energy-related CO₂, although in cumulative and per capita terms the United States will remain the largest for many years to come. Chinese CO₂ emissions have almost tripled between 1990 and 2008. The increases were especially large in the last six years (16% in 2003, 19% in 2004, 11% in both 2005 and 2006, and 8% in 2007 and 2008). The *WEO 2009* Reference Scenario projects that the growth in Chinese emissions will slow down to 2.9% per year up to 2030. Even with this slower growth, emissions in 2030 will be almost twice current levels, although policies are being considered that would reduce such growth considerably.

Since 1990, the electricity and heat generation sector grew the most, representing 48% of Chinese CO₂ emissions in 2008 (Figure 23). The transport sector also grew rapidly, but from a much smaller base, representing 7% in 2008. The *WEO 2009* Reference Scenario projects that the transport sector will continue to grow, rising to 12% in 2030, as switching to low- or zero-carbon energy sources is much more difficult in transport than in other sectors.

Figure 23. China: CO₂ emissions by sector

Key point: For the last six years, and in line with vigorous economic expansion, China showed dramatic growth in CO₂ emissions from electricity and heat generation.

Chinese demand for electricity was the largest driver of the rise in emissions. The rate of capacity additions

peaked in 2006, but in 2009 China's installed capacity rose by a net 81 GW (China Electricity Council, 2010), slightly more than the total installed capacity of South Korea. At the same time, it closed over 26 GW of small, inefficient fossil fuel-fired plants (Guobao, 2010), about the size of Ireland and Switzerland's combined installed capacity. Coal played a major role in supporting the growing demand for electricity generation (Figure 24). Nearly all of the 1990-2008 emissions growth from power generation derived from coal, although hydro increased its share in 2008 from 15% to 17%.

Figure 24. China: Electricity generation by fuel

Key point: Coal dominates China's electricity generation and its very fast growth, although hydro increased its share in 2008.

In the past few decades, China had experienced a rapid decoupling of energy consumption and CO₂ emissions from economic growth. During the 1980s, the central government in China reduced industrial energy intensity by establishing standards and quotas for the energy supplied to firms and had the authority to shut off the power supply when enterprises exceeded their limits (Lin, 2005). However, as the Chinese economy has moved towards an open-market operation, investment in energy conservation as a percentage of total energy investment gradually declined (IEA, 2006b).

The rapid expansion since 2003 of heavy industrial sectors to serve huge infrastructure investments and burgeoning demand for Chinese products from domestic and overseas consumers pushed up demand for fossil fuels. As a result, CO₂ emissions per unit of GDP actually rose from 2003 to 2005. Still, the 2008 TPES/GDP is 58% less than in 1990, and a recent push by the government to reduce energy intensity has

helped to resume the long-term intensity decline, albeit at a much slower rate than in the past. The increasing share of coal in power generation, however, despite some of the world's largest investments in renewables, means that a small decline in energy intensity may still be paired with an increase in emissions intensity, as was the case in 2003 and 2004. Although per capita emissions in China in 2008 were only about one-half that of the OECD average, they have more than doubled since 1990, with the largest increases occurring in the last six years. The country is seeking ways to limit growth in CO₂ emissions, though, and has announced regional pilot projects to find practical ways of implementing the national pledge, announced in late 2009 under the Copenhagen Accord, to reduce CO₂ emissions per unit of GDP by 40% to 45% in 2020 compared to 2005.

South Africa

South Africa currently relies heavily on fossil fuels as a primary energy source (87% in 2008); with coal providing most of it. Although South Africa accounted for 38% of CO₂ emissions from fuel combustion in Africa in 2008, it represented only 1.1% of the global total. The electricity and heat sector produced 63% of South Africa's CO₂ emissions in 2008 (Figure 25).

Figure 25. South Africa: CO₂ emissions by sector

Key point: The largest share of CO₂ emissions in South Africa comes from the electricity and heat sector, but growth remains moderate compared to some of the other BRICS countries.

Coal dominates the South African energy system, accounting for 71% of primary energy supply and nearly one-quarter of final energy consumption. In 2008, South Africa generated 94% of its electricity using coal (Figure 26). In South Africa's Long-Term

Mitigation Scenarios (LTMS), emissions would quadruple between 2003 and 2050 in the absence of radical energy-choice changes, dominated by energy-related emissions, notably from the electricity, industrial and transport sectors. One of the major climate change mitigation issues facing South Africa is to reduce its greenhouse-gas emissions from the power sector, primarily by reducing reliance on coal. South Africa is already taking steps to expand the use of both renewable and nuclear energy, to explore the use of carbon capture and storage (CCS) technologies, and to reduce energy demand through a nation-wide energy efficiency programme. South Africa's public utility Eskom also has a target to reduce dependence on conventional coal to 70% by 2025 and reduce greenhouse-gas emissions in absolute terms by 2050, as well as to provide at least 1 600 MW in renewable capacity by 2025 (mostly large-scale solar and wind).

Figure 26. South Africa: Electricity generation by fuel

Key point: South Africa relies almost solely on coal to produce its electricity.

Prices of commercial forms of energy in South Africa are, in general, quite low by international standards. Given the relatively lower rate of electrification (about 88% in urban areas and only 55% in rural areas in 2008), the direct use of commercial forms of energy by households is more limited. Biomass (especially wood) dominates energy use by rural households, generating health and safety problems as well as concerns about the sustainability of wood supplies. Over the last 18 years, per capita CO₂ emissions in South Africa have remained fairly constant while emissions per unit of GDP have decreased by 20%. South Africa aims to reduce greenhouse-gas emissions 34% below its business-as-usual (BAU) growth trajectory by 2020, increasing to 42% below the BAU trajectory by 2025.

Sustainable energy use requires global engagement

Trends in CO₂ emissions from fuel combustion illustrate the need for all countries to shape a more sustainable energy future. Special emphasis should first be on the industrialised nations that have the highest per capita incomes and that are responsible for the bulk of cumulative emissions. However, with the rapidly growing energy demand of developing countries, it is important that they also strive to use energy in a sustainable way. *ETP 2010* shows that enhancing energy efficiency and reducing the carbon intensity of energy supply, which is largely reliant on fossil fuels, are both fundamental steps towards a global low-carbon energy system.

Between 1971 and 2008, global CO₂ emissions doubled. However, two important turning points occurred in 2008: for the first time emissions from non-Annex I countries surpassed those of the Annex I countries and the emission levels of the Annex I countries were below 1990 levels (Figure 27) due to the economic contraction arising from the recession and high oil prices in 2008.

Figure 27. Trends in regional CO₂ emissions

Gt CO₂

* Asia includes Korea and excludes Japan (which is included in Annex II).

** Other includes Africa, Latin America, Middle East, non-Annex I EIT, Turkey, international bunkers, and, for 1971, Annex I EIT.

Key points: In 2008, CO₂ emissions from Annex I countries fell back to 1990 levels, while emissions from non-Annex I countries continued to grow. Also for the first time in 2008, the CO₂ emissions from non-Annex I countries surpassed those of Annex I countries.

The share of CO₂ emissions in Annex I countries to the UNFCCC (the sum of Annex II and Annex I EIT) progressively shrank (61% in 1971, 47% in 1990 and

37% in 2008), as emissions in developing countries (led by Asia) increased at a much faster rate. The growth in Asian emissions reflects a striking rate of economic development, particularly within China and India. Between 1990 and 2008, CO₂ emissions rose by 124% for non-Annex I countries as a whole and more than doubled for Asia. This is in contrast to the reduction in emissions to 1990 levels (-0.007% growth between 1990 and 2008) which occurred in the Annex I countries.

Emission trends within Annex I countries were very different. Emissions of CO₂ in Annex II countries in 2008 were actually 12% higher than in 1990. This growth was offset by emission reductions in the Annex I EIT countries. Emissions from the EIT countries followed a peculiar path due to a rapid decline in industrial productivity subsequent to the 1989 collapse of their centrally planned economies. Between 1990 and 2000, the EIT emissions declined by 36%. Emissions in the Former Soviet Union alone fell by over 1.4 Gt CO₂ (39%) between 1990 and 2000. However, this trend was reversed in recent years.

Since the Industrial Revolution, the bulk of annual CO₂ emissions have originated from industrialised countries. However, this long period of dominance will soon end given the size of some of the developing economies and the growth in their energy needs. Effective emissions mitigation will require all countries, regardless of energy demand and infrastructure, to use energy in a sustainable manner.

3. IEA EMISSIONS ESTIMATES

The estimates of CO₂ emissions from fuel combustion presented in this publication are calculated using the IEA energy data²³ and the default methods and emission factors from the *Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories*, IPCC/OECD/IEA, Paris, 1997 (*1996 IPCC Guidelines*).

Although the IPCC approved the *2006 Guidelines* at the 25th session of the IPCC in April 2006 in Mauritius, most countries (as well as the IEA Secretariat) are still calculating their inventories using the *1996 IPCC Guidelines*.

The IEA Secretariat reviews its energy databases each year. In the light of new assessments, important revisions may be made to the time series of individual countries. Therefore, certain data in this publication may have been revised with respect to previous editions.

Inventory quality

The *IPCC Guidelines* allow Parties under the UNFCCC to prepare and periodically update national inventories that are accurate, complete, comparable and transparent. Inventory quality is an important issue since countries are now implementing legally-binding commitments.

One way to assess inventory quality is to do comparisons among inventories, methodologies and input data. The *IPCC Guidelines* recommend that countries which have used a detailed Sectoral Approach for CO₂ emissions from energy combustion also use the Reference Approach for verification purposes. This will identify areas where a full accounting of emissions may not have been made (see Chapter 5 of the full-scale study).

Reference Approach vs. Sectoral Approach

The Reference Approach and the Sectoral Approach often give different results because the Reference Approach is a top-down approach using a country's energy supply data and has no detailed information on how the individual fuels are used in each sector.

The Reference Approach provides estimates of CO₂ to compare with estimates derived using a Sectoral Approach. Theoretically, it indicates an upper bound to the Sectoral Approach "1A fuel combustion", because some of the carbon in the fuel is not combusted but will be emitted as fugitive emissions (as leakage or evaporation in the production and/or transformation stage).

Calculating CO₂ emissions inventories with the two approaches can lead to different results for some countries. In general the gap between the two approaches is relatively small (5 per cent or less) when compared to the total carbon flows involved. In cases where 1) fugitive emissions are proportional to the mass flows entering production and/or transformation processes, 2) stock changes at the level of the final consumer are not significant and 3) statistical differences in the energy data are limited, the Reference Approach and the Sectoral Approach should lead to similar evaluations of the CO₂ emissions trends.

When significant discrepancies and/or large time-series deviations do occur, they may be due to various reasons such as:

Large statistical differences between the energy supply and the energy consumption in the basic energy data. Statistical differences arise from the collection of data from different parts of the fuel flow from its supply origins to the various stages of downstream conversion and use. They are a normal part of a fuel

23. Published in *Energy Statistics of OECD Countries, Energy Balances of OECD Countries, Energy Statistics of Non-OECD Countries and Energy Balances of Non-OECD Countries*, IEA, Paris, 2010.

balance. Large random statistical differences must always be examined to determine the reason for the difference, but equally importantly smaller statistical differences which systematically show an excess of supply over demand (or vice versa) should be pursued.

Significant mass imbalances between crude oil and other feedstock entering refineries and the (gross) petroleum products manufactured.

The use of aggregate net calorific and carbon content values for primary fuels which are converted rather than combusted. For example, it may appear that there is not conservation of energy or carbon depending on the calorific value and/or the carbon content chosen for the crude oil entering refineries and for the mix of products produced from the refinery for a particular year. This may cause an overestimation or underestimation of the emissions associated with the Reference Approach.

The misallocation of the quantities of fuels used for conversion into derived products (other than power or heat) **or quantities combusted in the energy sector.** When reconciling differences between the Reference Approach and a Sectoral Approach it is important to ensure that the quantities reported in the transformation and energy sectors (e.g. for coke ovens) reflect correctly the quantities used for conversion and for fuel use, respectively, and that no misallocation has occurred. Note that the quantities of fuels converted to derived products should have been reported in the transformation sector of the energy balance. If any derived products are used to fuel the conversion process, the amounts involved should have been reported in the energy sector of the energy balance. In a Sectoral Approach the inputs to the transformation sector should not be included in the activity data used to estimate emissions.

Missing information on certain transformation outputs. Emissions from combustion of secondary fuels produced in integrated processes (for example, coke oven gas) may be overlooked in a Tier 1 Sectoral Approach if data are poor or unavailable. The use of secondary fuels (the output from the transformation process) should be included in the Sectoral Approach. Failure to do so will result in an underestimation of the Sectoral Approach.

Simplifications in the Reference Approach. Certain quantities of carbon should be included in the Reference Approach because their emissions fall under fuel combustion. These quantities have been excluded where the flows are small or not represented by a major statistic available within energy data. Examples of quantities not accounted for in the Reference

Approach include lubricants used in two-stroke engines, blast furnace and other by-product gases which are used for fuel combustion outside their source category of production and combustion of waxed products in waste plants with heat recovery. On the other hand, certain flows of carbon should be excluded from the Reference Approach, but for reasons similar to the above no practical means can be found to exclude them without over complicating the calculations. These include coals and other hydrocarbons injected into blast furnaces as well as cokes used as reductants in the manufacture of inorganic chemicals. These simplifications will determine discrepancies between the Reference Approach and a Sectoral Approach. If data are available, the magnitudes of these effects can be estimated.

Missing information on stock changes that may occur at the final consumer level. The relevance of consumer stocks depends on the method used for the Sectoral Approach. If delivery figures are used (this is often the case) then changes in consumers' stocks are irrelevant. If, however, the Sectoral Approach is using actual consumption of the fuel, then this could cause either an overestimation or an underestimation of the Reference Approach.

High distribution losses or unrecorded consumption for gas may mean that the emissions are overestimated by the Reference Approach or underestimated by the Sectoral Approach.

The treatment of transfers and reclassifications of energy products may cause a difference in the Sectoral Approach estimation since different net calorific values and emission factors may be used depending on how the fuel is classified.

Differences between IEA estimates and UNFCCC submissions

It is possible to use the IEA CO₂ estimates for comparison with the greenhouse-gas inventories reported by countries to the UNFCCC Secretariat. In this way, problems in methods, input data or emission factors may become apparent. However, care should be used in interpreting the results of any comparison since the IEA estimates may differ from a country's official submission for many reasons.

A recent comparison of the IEA estimates with the inventories submitted to the UNFCCC showed that for most Annex II countries, the two calculations were

within 5%. For some EIT and non-Annex I countries, differences between the IEA estimates and national inventories were larger. In some of the countries the underlying energy data were different; suggesting that more work is needed on the collecting and reporting of energy statistics for those countries.

Some countries have incorrectly defined bunkers as fuel used abroad by their own ships and planes. Still other countries have made calculation errors for carbon oxidation or have included international bunkers in their totals. Since all of the above will affect the national totals of CO₂ emissions from fuel combustion, a systematic comparison with the IEA estimates would allow countries to verify their calculations and produce more internationally comparable inventories.

In addition, the main bias in the energy data and emission factors will probably be systematic and not random. This means that the emission trends will usually be more reliable than the absolute emission levels. By comparing trends in the IEA estimates with trends in emissions as reported to the UNFCCC, it should be possible to identify definition problems or changes in the calculations, which were not reflected in the base year.

For many reasons the IEA estimates may differ from the numbers that a country submits to the UNFCCC, even if a country has accounted for all of its energy use and correctly applied the *IPCC Guidelines*. No attempt has been made to quantify the effects of these differences. In most cases these differences will be relatively small. Some of the reasons for these differences are:

- **The IEA uses a Tier 1 method.**

The IEA uses a Tier 1 Sectoral Approach based on the *1996 IPCC Guidelines*. Countries may be using a Tier 2 or Tier 3 method that takes into account different technologies.

- **The IEA is using the 1996 IPCC Guidelines.**

The IEA is still using the *1996 IPCC Guidelines*. Some countries may have already started using the *2006 IPCC Guidelines*.

- **Energy activity data are extracted from the IEA energy balances and may differ from those used for the UNFCCC calculations.**

Countries often have several “official” sources of data such as a Ministry, a Central Bureau of Statistics, a nationalised electricity company, etc. Data can also be collected from the energy suppliers, the energy consumers or customs statistics. The IEA Secretariat tries to collect the most accurate data, but does not necessarily

have access to the complete data set that may be available to national experts calculating emission inventories for the UNFCCC. In addition to different sources, the methodology used by the national bodies providing the data to the IEA and to the UNFCCC may differ. For example, general surveys, specific surveys, questionnaires, estimations, combined methods and classifications of data used in national statistics and in their subsequent reclassification according to international standards may result in different series.

- **The IEA uses average net calorific values.**

The IEA uses an average net calorific value (NCV) for each secondary oil product. These NCVs are region-specific and constant over time. Country-specific NCVs that can vary over time are used for NGL, refinery feedstocks and additives. Crude oil NCVs are further split into production, imports, exports and average. Different coal types have specific NCVs for production, imports, exports, inputs to main activity power plants and coal used in coke ovens, blast furnaces and industry, and can vary over time for each country.

Country experts may have the possibility of going into much more detail when calculating the heat content of the fuels. This in turn could produce different values than the IEA.

- **The IEA uses average emission factors.**

The IEA uses the default emission factors which are given in the *1996 IPCC Guidelines*. Country experts may have better information available.

- **The IEA does not have detailed information for the stored carbon calculation.**

The IEA does not have complete information on the non-energy use of fuels. The amount of carbon stored is estimated using the default values given in the *1996 IPCC Guidelines*. For “other products” in the stored carbon calculation, the IEA assumes that 100% of kerosene, white spirit and petroleum coke that is reported as non-energy use in the energy balance is also stored. Country experts calculating the inventories may have more detailed information.

- **The IEA cannot allocate emissions from auto-producers into the end-use sectors.**

The *1996 IPCC Guidelines* recommend that emissions from autoproduction should be included with emissions from other fuel use by end-consumers. At the same time, the emissions from the autoproduction of electricity and heat should be excluded from the energy transformation source category to avoid double counting. The IEA is not able to allocate the fuel use

from autoproducers between the industrial and “other” sectors. Therefore, this publication shows a category called “Unallocated autoproducers”. However, this should not affect the total emissions for a country.

- **Military emissions may be treated differently.**

According to the *1996 IPCC Guidelines*, military emissions should be reported in Source/Sink Category 1 A 5, *Other (not elsewhere specified)*. Previously, the IEA questionnaires requested that warships be included in international marine bunkers and that the military use of aviation fuels be included in domestic air. All other military use should have been reported in *non-specified other sector*.

At the IEA/Eurostat/UNECE Energy Statistics Working Group meeting (Paris, November 2004), participants decided to harmonise the definitions used to collect energy data on the joint IEA/Eurostat/UNECE questionnaires with those used by the IPCC to report greenhouse-gas inventories. As a result, starting in the 2006 edition of this publication, all military consumption should be reported in non-specified other sectors. Sea-going versus coastal is no longer a criterion for splitting international and domestic navigation. For more information on the changes, please consult the Energy Statistics Working Group meeting report on our website at www.iea.org/Textbase/stats/questionnaire/index.asp.

However, it is not clear whether countries are reporting on the new basis, and if they are, whether they will be able to revise their historical data. The IEA has found that in practice most countries consider information on military consumption as confidential and therefore either combine it with other information or do not include it at all.

- **The IEA estimates include emissions from coke inputs into blast furnaces. Countries may have included these emissions in the IPCC category industrial processes.**

National greenhouse-gas inventories submitted to the UNFCCC divide emissions according to source categories. Two of these IPCC Source/Sink Categories are energy and industrial processes. The IPCC Reference Approach estimates national emissions from fuel combustion based on the supply of fuel to a country and by implication includes emissions from coke inputs to blast furnaces in the energy sector. However, within detailed sectoral calculations certain non-energy processes can be distinguished. In the reduction of iron in a blast furnace through the combustion of coke, the primary purpose of coke oxidation is to produce pig iron and the emissions can be considered as an industrial process. Care must be taken not to

double count these emissions in both energy and industrial processes. The IEA estimates of emissions from fuel combustion in this publication include the coke inputs to blast furnaces.

- **The units may be different.**

The *1996 IPCC Guidelines* and the *UNFCCC Reporting Guidelines on Annual Inventories* both ask that CO₂ emissions be reported in Gg of CO₂. A million tonnes of CO₂ is equal to 1 000 Gg of CO₂, so to compare the numbers in this publication with national inventories expressed in Gg, the IEA emissions must be multiplied by 1 000.

Key sources

In May 2000, the IPCC Plenary accepted the report on *Good Practice Guidance and Uncertainty Management in National Greenhouse Gas Inventories*. The report provides good practice guidance to assist countries in determining their key source categories. By identifying these key sources in the national inventory, inventory agencies can prioritise their efforts and improve their overall estimates.

The *Good Practice Guidance* identifies a key source category as one that is prioritised within the national inventory system because its estimate has a significant influence on a country’s total inventory of direct greenhouse gases in terms of the absolute level of emissions, the trend in emissions, or both.

For a more complete description of the IPCC methodology for determining key sources, see Chapter 5 of the full-scale study.

In the *Good Practice Guidance*, the recommendation for choosing the level of the key source analysis is to “disaggregate to the level where emission factors are distinguished. In most inventories, this will be the main fuel types. If emission factors are determined independently for some sub-source categories, these should be distinguished in the analysis.”

Since the emission estimates in this publication were produced using the default emission factors from the *1996 IPCC Guidelines*, this means that the fuel combustion categories would have been divided into:

- stationary combustion – coal
- stationary combustion – oil
- stationary combustion – gas
- mobile combustion – coal
- mobile combustion – oil
- mobile combustion – gas

Clearly this level of aggregation is not particularly useful in identifying where additional work is needed in refining the inventory. It does not take into account the possibility of improving data collection methods, improving emission factors or using a higher tier calculation for certain key sectors within the energy from fuel combustion source category. For this reason the IEA has disaggregated the key source analysis to the same level of detail presented in the country tables of this publication. For each country, the 11 largest sources, split by coal, oil, gas and other, are shown in the key sources table.

To calculate the level assessment, the IEA has started with the CO₂ emissions from fuel combustion as calculated by the IEA. To supplement this, where possible, the IEA has used the emissions that were submitted by the Annex I Parties to the UNFCCC in the 2010 submission of the Common Reporting Format for CO₂ (only fugitive), CH₄, N₂O, HFCs, PFCs and SF₆, not taking into account CO₂ emissions/removals from land use, land use change and forestry.²⁴

For the non-Annex I Parties, CO₂ emissions from fuel combustion were from the IEA and the rest of the 2008 emissions were estimated by PBL.

The cumulative contribution only includes the 11 largest key sources of CO₂ from fuel combustion. As a result, in most cases the cumulative contribution will not be 95% as recommended in the *Good Practice Guidance* and key sources from fugitive emissions, industrial processes, solvents, agriculture and waste will not be shown. The percentage of CO₂ emissions from fuel combustion in total greenhouse-gas emissions has been included as a memo item at the bottom of the table.

Notes on tables and graphs

Table of CO₂ emissions by sector

Row 1: *Sectoral Approach* contains total CO₂ emissions from fuel combustion as calculated using the IPCC Tier 1 Sectoral Approach and corresponds to IPCC Source/Sink Category 1 A. Emissions calculated using a Sectoral Approach include emissions only when the fuel is actually combusted.

Row 2: *Main activity producer electricity and heat* contains the sum of emissions from main activity producer electricity generation, combined heat and power generation and heat plants. Main activity producers (formerly known as public utilities) are defined as those undertakings whose primary activity is to supply the public. They may be publicly or privately owned. Emissions from own on-site use of fuel are included. This corresponds to IPCC Source/Sink Category 1 A 1 a.

Row 3: *Unallocated autoproducers* contains the emissions from the generation of electricity and/or heat by autoproducers. Autoproducers are defined as undertakings that generate electricity and/or heat, wholly or partly for their own use as an activity which supports their primary activity. They may be privately or publicly owned. In the *1996 IPCC Guidelines*, these emissions would normally be distributed between industry, transport and “other” sectors.

Row 4: *Other energy industries* contains emissions from fuel combusted in oil refineries, for the manufacture of solid fuels, coal mining, oil and gas extraction and other energy-producing industries. This corresponds to the IPCC Source/Sink Categories 1 A 1 b and 1 A 1 c. According to the *1996 IPCC Guidelines*, emissions from coke inputs to blast furnaces can either be counted here or in the industrial processes source/sink category. Within detailed sectoral calculations, certain non-energy processes can be distinguished. In the reduction of iron in a blast furnace through the combustion of coke, the primary purpose of the coke oxidation is to produce pig iron and the emissions can be considered as an industrial process. Care must be taken not to double count these emissions in both energy and industrial processes. In the IEA estimations, these emissions have been included in this category.

Row 5: *Manufacturing industries and construction* contains the emissions from combustion of fuels in industry. The IPCC Source/Sink Category 1 A 2 includes these emissions. However, in the *1996 IPCC Guidelines*, the IPCC category also includes emissions from industry autoproducers that generate electricity and/or heat. The IEA data are not collected in a way that allows the energy consumption to be split by specific end-use and therefore, this publication shows autoproducers as a separate item. See Row 3, *Unallocated autoproducers*. *Manufacturing industries and construction* also includes emissions from coke inputs into blast furnaces, which may be reported either in the transformation sector, the industry sector or the separate IPCC Source/Sink Category 2, industrial processes.

24. As recommended in the *Good Practice Guidance*.

Row 6: *Transport* contains emissions from the combustion of fuel for all transport activity, regardless of the sector, except for international marine bunkers and international aviation. This includes domestic aviation, domestic navigation, road, rail and pipeline transport, and corresponds to IPCC Source/Sink Category 1 A 3. In addition, the IEA data are not collected in a way that allows the autoproducer consumption to be split by specific end-use and therefore, this publication shows autoproducers as a separate item. See Row 3, *Unallocated autoproducers*.

Note: Starting in the 2006 edition, military consumption previously included in *domestic aviation* and in *road* should be in *non-specified other sectors*. See the section on Differences between IEA estimates and UNFCCC submissions, for further details.

Row 7: *Road* contains the emissions arising from fuel use in road vehicles, including the use of agricultural vehicles on highways. This corresponds to the IPCC Source/Sink Category 1 A 3 b.

Row 8: *Other Sectors* contains the emissions from commercial/institutional activities, agriculture/forestry, fishing, residential and other emissions not specified elsewhere that are included in the IPCC Source/Sink Categories 1 A 4 and 1 A 5. In the 1996 IPCC Guidelines, the category also includes emissions from autoproducers in the commercial/residential/agricultural sectors that generate electricity and/or heat. The IEA data are not collected in a way that allows the energy consumption to be split by specific end-use and therefore, this publication shows autoproducers as a separate item. See Row 3, *Unallocated autoproducers*.

Row 9: *Residential* contains all emissions from fuel combustion in households. This corresponds to IPCC Source/Sink Category 1 A 4 b.

Row 10: *Reference Approach* contains total CO₂ emissions from fuel combustion as calculated using the IPCC Reference Approach. The Reference Approach is based on the supply of energy in a country and as a result, all inventories calculated using this method include fugitive emissions from energy transformation (e.g. from oil refineries) which are normally included in Category 1 B. For this reason, Reference Approach estimates are likely to overestimate national CO₂ emissions. In these tables, the difference between the Sectoral Approach and the Reference Approach includes statistical differences, product transfers, transformation losses and distribution losses.

Row 11: *Differences due to losses and/or transformation* contains emissions that result from the transformation of energy from a primary fuel to a secondary or tertiary fuel. Included here are solid fuel transformation, oil refineries, gas works and other fuel transformation industries. These emissions are normally reported as fugitive emissions in the IPCC Source/Sink Category 1 B, but will be included in 1 A in inventories that are calculated using the IPCC Reference Approach. Theoretically, this category should show relatively small emissions representing the loss of carbon by other ways than combustion, such as evaporation or leakage.

Negative emissions for one product and positive emissions for another product would imply a change in the classification of the emission source as a result of an energy transformation between coal and gas, between coal and oil, etc. In practice, however, it often proves difficult to correctly account for all inputs and outputs in energy transformation industries, and to separate energy that is transformed from energy that is combusted. Therefore, the row *Differences due to losses and/or transformation* sometimes shows quite large positive emissions or even negative ones due to problems in the underlying energy data.

Row 12: *Statistical differences* can be due to unexplained discrepancies in the underlying energy data. They can also be caused by differences between emissions calculated using the Reference Approach and the Sectoral Approach.

Row 13: *International marine bunkers* contains emissions from fuels burned by ships of all flags that are engaged in international navigation. The international navigation may take place at sea, on inland lakes and waterways, and in coastal waters. Consumption by ships engaged in domestic navigation is excluded. The domestic/international split is determined on the basis of port of departure and port of arrival, and not by the flag or nationality of the ship. Consumption by fishing vessels and by military forces is also excluded. Emissions from international marine bunkers should be excluded from the national totals. This corresponds to IPCC Source/Sink Category 1 A 3 d i.

Row 14: *International aviation* contains emissions from fuels used by aircraft for international aviation. Fuels used by airlines for their road vehicles are excluded. The domestic/international split should be determined on the basis of departure and landing locations and not by the nationality of the airline.

Emissions from international aviation should be excluded from the national totals. This corresponds to IPCC Source/Sink Category 1 A 3 a i.

Figures 2 and 3: Emissions by sector

The sector *Other* includes emissions from commercial and public services, agriculture/forestry and fishing. Emissions from unallocated autoproducers are included in *Electricity and heat*.

Figure 5: Electricity generation by fuel

The product *Other* includes geothermal, solar, wind, combustible renewables and waste, etc. Electricity generation includes both main activity producer and autoproducer electricity.

Country notes

Cuba

International marine bunkers for residual fuel oil in the period 1971-1983 were estimated on the basis of 1984 figures and the data reported as domestic navigation in the energy balance.

Cyprus

Note by Turkey:

The information in this document with reference to “Cyprus” relates to the southern part of the Island. There is no single authority representing both Turkish and Greek Cypriot people on the Island. Turkey recognises the Turkish Republic of Northern Cyprus (TRNC). Until a lasting and equitable solution is found within the context of the United Nations, Turkey shall preserve its position concerning the “Cyprus” issue.

Note by all the European Union Member States of the OECD and the European Commission:

The Republic of Cyprus is recognised by all members of the United Nations with the exception of Turkey. The information in this report relates to the area under the effective control of the Government of the Republic of Cyprus.

Estonia

The data reported as lignite in the energy balance have been considered as oil shale for the calculation of CO₂ emissions.

France

The methodology for calculating main activity electricity and heat production from gas changed in 2000.

Israel

The statistical data for Israel are supplied by and under the responsibility of the relevant Israeli authorities. The use of such data by the OECD is without prejudice to the status of the Golan Heights, East Jerusalem and Israeli settlements in the West Bank under the terms of international law.

Italy

Prior to 1990, gas use in commercial/public services was included in residential.

Japan

For four consecutive years, the IEA received revisions from the Japanese Administration. The first set of revisions received in 2004 increased the 1990 supply by 5% for coal, 2% for natural gas and 0.7% for oil compared to the previous data. This led to an increase of 2.5% in 1990 CO₂ emissions calculated using the Reference Approach while the Sectoral Approach remained fairly constant. For the 2006 edition, the IEA received revisions to the coal and oil data which had a significant impact on both the energy data and the CO₂ emissions. The most significant revisions occurred for coke oven coke, naphtha, blast furnace gas and petroleum coke. These revisions affected consumption rather than supply in the years concerned. As a result, the sectoral approach CO₂ emissions increased for all the years, however at different rates. For example, the sectoral approach CO₂ emissions for 1990 were 4.6% higher than those calculated for the 2005 edition while the 2003 emissions were 1.1% higher than those of the previous edition. Due to the impact these successive revisions have had on the final energy balance as well as on CO₂ emissions, the IEA was in close contact with the Japanese Administration to better understand the reasons behind these changes. These changes are mainly due to the Government of Japan's efforts to improve the input-output balances in the production of oil products and coal products in response to inquiries from the UNFCCC Secretariat. To cope with this issue, the Japanese Administration established a working group in March 2004. The working group completed its work in April 2006. Many of its conclusions were incorporated in the 2006 edition but some further

revisions to the time series (especially in industry and other sectors) were submitted for the 2007 edition.

Netherlands Antilles

Prior to 1992, the Reference Approach overstates emissions since data for lubricants and bitumen (which store carbon) are not available.

Norway

Discrepancies between Reference and Sectoral Approach estimates and the difference in the resulting growth rates arise from statistical differences between supply and consumption data for oil and natural gas. For Norway, supply of these fuels is the residual of two very large and opposite terms, production and exports.

Switzerland

The sectoral breakdown for gas/diesel oil used in the residential sector before 1978 was estimated on the basis of commercial and residential consumption in 1978 and the data reported as commercial consumption in the energy balance in previous years.

United Kingdom

For reasons of confidentiality, gas for main activity electricity is included in autoproducers for 1990.

Vietnam

A detailed sectoral breakdown is available starting in 1980.

4. INDICATORS

Population

The main source of the 1970 to 2008 population data for the OECD member countries is *National Accounts of OECD Countries, Volume 1*, OECD, Paris, 2010. Data for 1960 to 1969 have been estimated using the growth rates from the population series published in the *OECD Economic Outlook No. 76*. For the **Czech Republic, Hungary and Poland** (1960 to 1969) and **Mexico** (1960 to 1962), the data are estimated using the growth rates from the population series from the World Bank published in the *World Development Indicators CD-ROM*. For the **Slovak Republic**, population data for 1960 to 1989 are from the Demographic Research Centre, Infostat, Slovak Republic.

The main source of the population data for the OECD non-member countries is *World Development Indicators*, World Bank, Washington D.C., 2010. Population data for **Chinese Taipei, Gibraltar, Iraq** and a few countries within the regions²⁵ **Other Africa, Other Latin America** and **Other Asia** are based on the CHELEM-CEPII online database, 2010.

GDP

The main source of the 1970 to 2008 GDP series for the OECD member countries is *National Accounts of OECD Countries, Volume 1*, 2010. GDP data for 1960 to 1969 have been estimated using the growth rates from the series in the *OECD Economic Outlook No 76* and data previously published by the OECD Secretariat. Data prior to 1990 for the **Czech Republic** and **Poland**, prior to 1991 for **Hungary**, and prior to 1992 for the **Slovak Republic** are IEA Secretariat estimates based on GDP growth rates from the World Bank.

The main source of the GDP series for the non-OECD member countries is *World Development Indicators*, World Bank, Washington D.C., 2010. GDP figures for **Bosnia and Herzegovina, Brunei Darussalam, Chinese Taipei, Cuba, Gibraltar, Iraq, Democratic People's Republic of Korea, Libyan Arab Jamahiriya, Myanmar, Namibia** (1971-1979), **Netherlands Antilles** (available from 1980), **Qatar, Former Soviet Union** (before 1990), **Former Yugoslavia** (before 1990) and a few countries within the regions²⁵ **Other Africa, Other Latin America** and **Other Asia** are from the CHELEM-CEPII online databases 2009, 2010. GDP figures for **Albania** (1971-1979), **Angola** (1971-1984), **Bahrain** (1971-1979, 2006-2008), **Bosnia and Herzegovina** (1990-1993), **Brunei Darussalam** (1971-1973, 2008), **Bulgaria** (1971-1979), **Cyprus** (2008), **Ethiopia** (1971-1980), **Jordan** (1971-1974), **Kuwait** (1990-1991, 2007-2008), **Lebanon** (1971-1987), **Malta** (2008), **Mozambique** (1971-1979), **Oman** (2006-2008), **Romania** (1971-1979), **Serbia**²⁶ (1990-1998), **United Republic of Tanzania** (1971-1987), the **United Arab Emirates** (1971-1972 and 2007-2008), **Vietnam** (1971-1983), **Yemen** (1971-1989) and **Zimbabwe** (2006-2008) have been estimated based on the growth rates of the CHELEM-CEPII online database, 2010.

The GDP data have been compiled for individual countries at market prices in local currency and annual rates. These data have been scaled up/down to the price levels of 2000 and then converted to US dollars

25. Due to lack of complete time series, figures for population and for GDP of Other Latin America do not include British Virgin Islands, Cayman Islands, Falkland Islands, Martinique, Montserrat, Saint Pierre and Miquelon, and Turks and Caicos Islands; and figures for population and GDP of Other Asia do not include Cook Islands.

26. Data for GDP for Serbia include Montenegro until 2004.

using the yearly average 2000 exchange rates or purchasing power parities (PPPs).²⁷

For the OECD member countries, the PPPs selected to convert the GDP from national currencies to US dollars come from the OECD Secretariat and were aggregated using the Geary-Khamis (GK) method and rebased on the United States. For a more detailed description of the methodology please see *Purchasing Power Parities and Real Expenditures, GK Results, Volume II, 1990*, OECD, 1993. The PPPs for the other countries come from the World Bank and CHELEM-CEPII.

For the OECD non-member countries, while both the World Bank and CHELEM-CEPII rebased their GDP PPP time series on 2005, this publication shows GDP data on a 2000 basis. Therefore, only time series of GDP PPP 2000 USD were obtained by applying the ratio GDP 2000 USD to GDP PPP 2000 USD of last year's edition to the new GDP 2000 USD figures.

CO₂ emissions

The estimates of CO₂ emissions in this publication are based on the 1996 IPCC Guidelines and represent the total emissions from fuel combustion. Emissions have been calculated using both the IPCC Reference Approach and the IPCC Sectoral Approach (which corresponds to IPCC Source/Sink Category 1 A). Reference Approach totals may include certain fugitive emissions from energy transformation which should normally be included in Category 1 B. National totals do not include emissions from international marine bunkers and international aviation. See Chapter 3, IEA emissions estimates for further details.

Total primary energy supply

Total primary energy supply (TPES) is made up of production + imports - exports - international marine bunkers - **international aviation bunkers** ± stock changes.

27. Purchasing power parities are the rates of currency conversion that equalise the purchasing power of different currencies. A given sum of money, when converted into different currencies at the PPP rates, buys the same basket of goods and services in all countries. In other words, PPPs are the rates of currency conversion which eliminate the differences in price levels between different countries.

Note: In October 2008 the IEA hosted the third meeting of InterEnerStat. This group is made up of 24 international organisations that collect or use energy statistics. One of the objectives of the group is to improve the quality of energy data by harmonising definitions for energy sources and flows. As a result of this meeting, the IEA has decided to align its energy statistics and balances with most other international organisations and to treat international aviation bunkers in the same way as international marine bunkers. Starting with the 2009 edition, international aviation bunkers is subtracted out of supply in the same way as international marine bunkers.

Electricity and heat output

Total output (shown in the summary tables section) includes electricity and heat generated in the transformation sector using fossil fuels, nuclear, hydro (excluding pumped storage), geothermal, solar, biomass, etc.

Both **main activity**²⁸ **producer** (formerly known as public) and **autoproducer**²⁹ **plants** have been included where available.

For electricity, data include the total number of TWh generated by both **electricity plants** and **CHP plants**.

For heat, data include the total amount of TJ generated by both **CHP plants** and **heat plants**.

To calculate the total electricity and heat output, the heat generated in TJ has been converted to TWh using the relationship 1 TWh = 3 600 TJ and added to electricity generated.

Ratios

CO₂ / TPES: This ratio is expressed in tonnes of CO₂ per terajoule. It has been calculated using the Sectoral Approach CO₂ emissions and total primary energy supply (including biomass and other non-fossil forms of energy).

28. Main activity producers (formerly known as public supply undertakings) generate electricity and/or heat for sale to third parties, as their primary activity. They may be privately or publicly owned. Note that the sale need not take place through the public grid.

29. Autoproducer undertakings generate electricity and/or heat, wholly or partly for their own use as an activity which supports their primary activity. They may be privately or publicly owned.

CO₂ / GDP: This ratio is expressed in kilogrammes of CO₂ per 2000 US dollar. It has been calculated using the Sectoral Approach CO₂ emissions and is shown with both GDP calculated using exchange rates and GDP calculated using purchasing power parities.

CO₂ / population: This ratio is expressed in tonnes of CO₂ per capita. It has been calculated using the Sectoral Approach CO₂ emissions.

Per capita CO₂ emissions by sector: These ratios are expressed in kilogrammes of CO₂ per capita. They have been calculated in two different ways. In the first ratio, the emissions from electricity and heat production are shown separately. In the second ratio, the emissions from electricity and heat have been allocated to final consuming sectors in proportion to the electricity and heat consumed by those sectors.

CO₂ emissions per kWh: These ratios are expressed in grammes of CO₂ per kWh. They have been calculated using CO₂ emissions from electricity and heat as shown in the country tables in the rows “main activity producer electricity and heat” and “unallocated autoproducers”, and electricity and heat output as described above.

In the first table on CO₂ emissions per kWh, the CO₂ emissions include emissions from fossil fuels, industrial waste and non-renewable municipal waste that are consumed for electricity and heat generation in the transformation sector and output includes electricity and heat generated from fossil fuels, nuclear, hydro (excluding pumped storage), geothermal, solar, biomass, etc. As a result, the emissions per kWh can vary from year to year depending on the generation mix.

In the ratios of CO₂ emissions per kWh **by fuel**:

- **Coal/peat** includes primary and secondary coal, peat and manufactured gases (excluding gas works gas).
- **Oil** includes petroleum products (and small amounts of crude oil for some countries).
- **Gas** includes natural gas and gas works gas.

Note: Emissions per kWh should be used with caution due to data quality problems relating to electricity efficiencies for some countries.

Implied emission factors from electricity and heat generation

Summary tables presenting CO₂ emissions per kWh from electricity and heat generation by country are presented in Part II. However, these values will vary enormously depending on the fuel mix of individual countries. Average implied emission factors by individual product for this sector are presented below. These values represent the average grammes of CO₂ per kWh of electricity and heat produced in the OECD member countries between 2006 and 2008. These figures will reflect any problems that may occur in net calorific values or in input/output efficiencies. Consequently, these values are given as an approximation and actual values may vary considerably.

Fuel	g CO ₂ / kWh
Anthracite *	840
Coking coal *	720
Other bituminous coal	840
Sub-bituminous coal	930
Lignite/brown coal	940
Patent fuel	880
Coke oven coke *	540
BKB/peat briquettes *	500-1100
Gas works gas *	400
Coke oven gas *	370
Blast furnace gas *	2100
Oxygen steel furnace gas *	1900
Natural gas	370
Crude oil *	640
Natural gas liquids *	700
Liquefied petroleum gases *	650
Kerosene *	640
Gas/diesel oil *	670
Residual fuel oil	635
Petroleum coke *	960
Peat *	570
Industrial waste *	450-2000
Municipal waste (non-renewable)*	450-2000

* These fuels represent less than 1% of electricity and heat output in the OECD. Values will be less reliable and should be used with caution.

5. GEOGRAPHICAL COVERAGE

Africa includes Algeria, Angola, Benin, Botswana (from 1981), Cameroon, Congo, Democratic Republic of Congo, Côte d'Ivoire, Egypt, Eritrea, Ethiopia, Gabon, Ghana, Kenya, Libyan Arab Jamahiriya, Morocco, Mozambique, Namibia (from 1991), Nigeria, Senegal, South Africa, Sudan, United Republic of Tanzania, Togo, Tunisia, Zambia, Zimbabwe and **Other Africa**.

Other Africa includes Botswana (until 1980), Burkina Faso, Burundi, Cape Verde, Central African Republic, Chad, Comoros, Djibouti, Equatorial Guinea, Gambia, Guinea, Guinea-Bissau, Lesotho, Liberia, Madagascar, Malawi, Mali, Mauritania, Mauritius, Namibia (until 1990), Niger, Reunion, Rwanda, Sao Tome and Principe, Seychelles, Sierra Leone, Somalia, Swaziland, Uganda and Western Sahara (from 1990).

Middle East includes Bahrain, Islamic Republic of Iran, Iraq, Israel³⁰, Jordan, Kuwait, Lebanon, Oman, Qatar, Saudi Arabia, Syrian Arab Republic, United Arab Emirates and Yemen.

Non-OECD Europe includes Albania, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus³¹, Gibraltar, Former Yugoslav Republic of Macedonia (FYROM), Malta, Romania, Serbia³², and Slovenia.

Former Soviet Union includes Armenia, Azerbaijan, Belarus, Estonia, Georgia, Kazakhstan, Kyrgyzstan, Latvia, Lithuania, Republic of Moldova, Russian Federation, Tajikistan, Turkmenistan, Ukraine and Uzbekistan.

Latin America includes Argentina, Bolivia, Brazil, Chile³³, Colombia, Costa Rica, Cuba, Dominican Republic, Ecuador, El Salvador, Guatemala, Haiti, Honduras, Jamaica, Netherlands Antilles, Nicaragua, Panama, Paraguay, Peru, Trinidad and Tobago, Uruguay, Venezuela and **Other Latin America**.

Other Latin America includes Antigua and Barbuda, Aruba, Bahamas, Barbados, Belize, Bermuda, British Virgin Islands, Cayman Islands, Dominica, Falkland Islands, French Guyana, Grenada, Guadeloupe, Guyana, Martinique, Montserrat, Puerto Rico³⁴ (for natural gas and electricity), St. Kitts and Nevis, Saint Lucia, Saint Pierre et Miquelon, St. Vincent and the Grenadines, Suriname and Turks/Caicos Islands.

China includes the People's Republic of China and Hong Kong (China).

Asia includes Bangladesh, Brunei Darussalam, Cambodia (from 1995), Chinese Taipei, India, Indonesia, DPR of Korea, Malaysia, Mongolia (from 1985), Myanmar, Nepal, Pakistan, Philippines, Singapore, Sri Lanka, Thailand, Vietnam and **Other Asia**.

Other Asia includes Afghanistan, Bhutan, Cambodia (until 1994), Cook Islands, East Timor, Fiji, French Polynesia, Kiribati, Laos, Macau, Maldives, Mongolia (until 1984), New Caledonia, Palau (from 1994), Papua New Guinea, Samoa, Solomon Islands, Tonga and Vanuatu.

30. See the note concerning Israel in Chapter 3.

31. See the note concerning Cyprus in Chapter 3.

32. Serbia includes Montenegro until 2004 and Kosovo until 1999.

33. Chile became a member country of the OECD with effect from 7 May 2010. Since the preparation of the annual statistics publications was well on its way at that stage, data for Chile have not been included in OECD totals for the 2010 edition and will continue to be included in Latin America with the OECD non-member countries. The IEA Secretariat will work closely with the Chilean Administration, especially on the consistency of the time series, to incorporate Chile into OECD totals in the 2011 edition.

34. Oil statistics as well as coal trade statistics for Puerto Rico are included under the United States.

The **Organisation for Economic Co-Operation and Development**¹¹ (OECD) includes Australia, Austria, Belgium, Canada, the Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Japan, Korea, Luxembourg, Mexico, the Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic, Spain, Sweden, Switzerland, Turkey, the United Kingdom and the United States.

Within the **OECD**:

Australia excludes the overseas territories.

Denmark excludes Greenland and the Danish Faroes, except prior to 1990, where data on oil for Greenland were included with the Danish statistics. The Administration is planning to revise the series back to 1974 to exclude these amounts.

France includes Monaco, and excludes the following overseas departments and territories (Guadeloupe, Guyana, Martinique, New Caledonia, French Polynesia, Reunion and St.-Pierre and Miquelon).

Germany includes the new federal states of Germany from 1970 onwards.

Italy includes San Marino and the Vatican.

Japan includes Okinawa.

The **Netherlands** excludes Suriname and the Netherlands Antilles.

Portugal includes the Azores and Madeira.

Spain includes the Canary Islands.

Switzerland includes Liechtenstein for the oil data. Data for other fuels do not include Liechtenstein.

Shipments of coal and oil to the Channel Islands and the Isle of Man from the **United Kingdom** are not classed as exports. Supplies of coal and oil to these islands are, therefore, included as part of UK supply. Exports of natural gas to the Isle of Man are included with the exports to Ireland.

United States includes the 50 states and the District of Columbia. Oil statistics as well as coal trade statistics also include Puerto Rico³⁵, Guam, the Virgin Islands, American Samoa, Johnston Atoll, Midway Islands, Wake Island and the Northern Mariana Islands.

The **European Union - 27 (EU-27)** includes Austria, Belgium, Bulgaria, Cyprus, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, the Slovak Republic, Slovenia, Spain, Sweden and the United Kingdom.

The **International Energy Agency (IEA)** includes Australia, Austria, Belgium, Canada, the Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Japan, Korea, Luxembourg, the Netherlands, New Zealand, Norway, Poland, Portugal, the Slovak Republic, Spain, Sweden, Switzerland, Turkey, the United Kingdom and the United States.

Annex I Parties include Australia, Austria, Belarus, Belgium, Bulgaria, Canada, Croatia, the Czech Republic³⁶, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Japan, Latvia, Liechtenstein (not available in this publication), Lithuania, Luxembourg, Monaco (included with France), the Netherlands, New Zealand, Norway, Poland, Portugal, Romania, Russian Federation, the Slovak Republic³⁶, Slovenia, Spain, Sweden, Switzerland, Turkey, Ukraine, the United Kingdom and the United States.

The countries that are listed above are included in Annex I of the United Nations Framework Convention on Climate Change as amended on 11 December 1997 by the 12th Plenary meeting of the Third Conference of the Parties in Decision 4/CP.3. This includes the countries that were members of the OECD at the time of the signing of the Convention, the EEC, and fourteen countries in Central and Eastern Europe and the Former Soviet Union that are undergoing the process of transition to market economies.

Annex II Parties include Australia, Austria, Belgium, Canada, Denmark, Finland, France, Germany, Greece, Iceland, Ireland, Italy, Japan, Liechtenstein (not available in this publication), Luxembourg, Monaco (included with France), the Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, Switzerland, the United Kingdom and the United States.

According to Decision 26/CP.7 in document FCCC/CP/2001/13/Add.4, Turkey has been deleted from the list of Annex II countries to the Convention. This amendment entered into force on 28 June 2002.

35. Natural gas and electricity data for Puerto Rico are included under Other Latin America.

36. Czechoslovakia was in the original list of Annex I countries.

Economies in Transition (EITs) are those countries in Annex I that are undergoing the process of transition to a market economy. This includes Belarus, Bulgaria, Croatia, the Czech Republic³⁶, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Russian Federation, the Slovak Republic³⁶, Slovenia and Ukraine.

Annex I Kyoto Parties include Australia, Austria, Belgium, Bulgaria, Canada, Croatia, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Japan, Latvia, Liechtenstein (not available in this publication), Lithuania, Luxembourg, Monaco (included with France), the Netherlands, New Zealand, Norway, Poland, Portugal, Romania, Russian Federation, the Slovak Republic, Slovenia, Spain, Sweden, Switzerland, Ukraine and the United Kingdom.

Membership in the Kyoto Protocol is almost identical to that of Annex I, except for Turkey and Belarus which did not agree to a target under the Protocol and the United States which has expressed the intention not to ratify the Protocol. Australia ratified the Protocol on 12 December 2007 and has been included in the Kyoto aggregate in this edition.

Please note that the following countries have not been considered due to lack of data:

Africa: Saint Helena.

America: Anguilla.

Asia and Oceania: Christmas Island, Nauru and Niue.

Non-OECD Europe: Liechtenstein³⁷ (except for oil data) and Montenegro³⁸ (after 2004).

37. Oil data for Liechtenstein are included under Switzerland.

38. Data for Montenegro are included under Serbia until 2004.

6. SUMMARY TABLES

CO₂ emissions: Sectoral Approachmillion tonnes of CO₂

	1971	1975	1980	1985	1990	1995	2000	2005	2006	2007	2008	% change 90-08

* This table shows CO₂ emissions for the same sectors which are present throughout this publication. In particular, the emissions from electricity and heat production are shown separately and not reallocated as in the table on pages 68-70.

** Includes emissions from own use in petroleum refining, the manufacture of solid fuels, coal mining, oil and gas extraction and other energy-producing industries.

*** World includes international bunkers in the transport sector.

* CO₂ emissions from electricity and heat generation have been allocated to final consuming sectors in proportion to the electricity and heat consumed. The detailed unallocated emissions are shown in the table on pages 65-67.

** Includes emissions from own use in petroleum refining, the manufacture of solid fuels, coal mining, oil and gas extraction and other energy-producing industries.

*** World includes international bunkers in the transport sector.

CO₂ emissions with electricity and heat allocated to consuming sectors in 2008million tonnes of CO₂

* This table shows per capita emissions for the same sectors which are present throughout this publication. In particular, the emissions from electricity and heat production are shown separately and not reallocated as in the table on pages 101-103.

** Includes emissions from own use in petroleum refining, the manufacture of solid fuels, coal mining, oil and gas extraction and other energy-producing industries.

* Emissions from electricity and heat generation have been allocated to final consuming sectors in proportion to the electricity and heat consumed. The detailed unallocated emissions are shown in the table on pages 98-100.

** Includes emissions from own use in petroleum refining, the manufacture of solid fuels, coal mining, oil and gas extraction and other energy-producing industries.

* CO₂ emissions from fossil fuels consumed for electricity, combined heat and power and main activity heat plants divided by the output of electricity and heat generated from fossil fuels, nuclear, hydro (excl. pumped storage), geothermal, solar and biomass. Both main activity producers and autoproducers have been included in the calculation of the emissions. Due to missing data for heat in 1990, the ratio for some countries and regions is not available.

CO₂ emissions per kWh from electricity and heat generationgrammes CO₂ / kilowatt hour

* CO₂ emissions from coal consumed for electricity, combined heat and power and main activity heat plants divided by output of electricity and heat generated from coal. Both main activity producers and autoproducers have been included in the calculation of the emissions. Due to missing data for heat in 1990, the ratio for some countries and regions is not available.

CO₂ emissions per kWh from electricity and heat generation using coal/peatgrammes CO₂ / kilowatt hour

* CO₂ emissions from gas consumed for electricity, combined heat and power and main activity heat plants divided by output of electricity and heat generated from gas. Both main activity producers and autoproducers have been included in the calculation of the emissions. Due to missing data for heat in 1990, the ratio for some countries and regions is not available.

CO₂ emissions per kWh from electricity and heat generation using gasgrammes CO₂ / kilowatt hour

<i>Memo: total CO₂ from fuel combustion</i>	<i>29 381.4</i>	<i>40.1%</i>	<i>68.2</i>	<i>68.2</i>

*** Percent calculated using the total GHG estimate for CO₂, CH₄, N₂O, HFCs, PFCs and SF₆ excluding CO₂ emissions/removals from land use change and forestry.

Energy Data Manager / Statistician

Possible Staff Vacancies

International Energy Agency, Paris, France

The IEA

The International Energy Agency, based in Paris, acts as energy policy advisor to 28 member countries in their effort to ensure reliable, affordable and clean energy for their citizens. Founded during the oil crisis of 1973-74, the IEA's initial role was to co-ordinate measures in times of oil supply emergencies. As energy markets have changed, so has the IEA. Its mandate has broadened to incorporate the "Three E's" of balanced energy policy making: energy security, economic development and environmental protection. Current work focuses on climate change policies, market reform, energy technology collaboration and outreach to the rest of the world, especially major consumers and producers of energy like China, India, Russia and the OPEC countries.

The Energy Statistics Division, with a staff of around 30 people, provides a dynamic environment for young people just finishing their studies or with one to two years of work experience.

Job description

The data managers/statisticians compile, verify and disseminate information on all aspects of energy including production, transformation and consumption of all fuels, renewables, the emergency reporting system, energy efficiency indicators, CO₂ emissions, and energy prices and taxes. The data managers are responsible for receiving, reviewing and inputting data submissions from Member countries and other sources into large computerised databases. They check for completeness, correct calculations, internal consistency, accuracy and consistency with definitions. Often this entails proactively investigating and helping to resolve anomalies in collaboration with national administrations of Member and Non-Member countries. The data managers/statisticians also play a key role in helping to design and implement computer macros used in the preparation of their energy statistics publication(s).

Principal Qualifications

- University degree in a topic relevant to energy, computer programming or statistics. We currently have staff with degrees in Mathematics, Statistics, Information Technology, Economics, Engineering, Physics, Chemistry, Environmental Studies, Hydrology, Public Administration and Business.
- Experience in the basic use of databases and computer software. Good computer programming skills in Visual Basic.
- Ability to work accurately, pay attention to detail and work to deadlines. Ability to deal simultaneously with a wide variety of tasks and to organise work efficiently.
- Good communication skills; ability to work well in a team and in a multicultural environment, particularly in liaising with contacts in national administrations and industry.
- Very good knowledge of one of the two official languages of the Organisation (English or French). Knowledge of other languages would be an advantage.
- Some knowledge of energy industry operations and terminology would also be an advantage, but is not required.

Nationals of any OECD Member country are eligible for appointment. Basic salaries start at 3 000 Euros per month. The possibilities for advancement are good for candidates with appropriate qualifications and experience. Tentative enquiries about future vacancies are welcomed from men and women with relevant qualifications and experience. Applications in French or English, accompanied by a curriculum vitae, should be sent to:

Personnel and Finance Division
International Energy Agency
9 rue de la Fédération
75739 Paris Cedex 15, France
Email: recruitment@iea.org

On-Line Data Services

Users can instantly access not only all the data published in this book, but also all the time series used for preparing this publication and all the other statistics publications of the IEA. The data are available on-line, either through annual subscription or pay-per-view access. More information on this service can be found on our website: <http://data.iea.org>

Ten Annual Publications

■ Energy Statistics of OECD Countries, 2010 Edition

No other publication offers such in-depth statistical coverage. It is intended for anyone involved in analytical or policy work related to energy issues. It contains data on energy supply and consumption in original units for coal, oil, natural gas, combustible renewables/wastes and products derived from these primary fuels, as well as for electricity and heat. Complete data are available for 2007 and 2008 and supply estimates are available for the most recent year (*i.e.* 2009). Historical tables summarise data on production, trade and final consumption. Each issue includes definitions of products and flows and explanatory notes on the individual country data.

Published July 2010 - Price €120

■ Energy Balances of OECD Countries, 2010 Edition

A companion volume to *Energy Statistics of OECD Countries*, this publication presents standardised energy balances expressed in million tonnes of oil equivalent. Energy supply and consumption data are divided by main fuel: coal, oil, gas, nuclear, hydro, geothermal/solar, combustible renewables/wastes, electricity and heat. This allows for easy comparison of the contributions each fuel makes to the economy and their interrelationships through the conversion of one fuel to another. All of this is essential for estimating total energy supply, forecasting, energy conservation, and analysing the potential for interfuel substitution. Complete data are available for 2007 and 2008 and supply estimates are available for the most recent year (*i.e.* 2009). Historical tables summarise key energy and economic indicators as well as data on production, trade and final consumption. Each issue includes definitions of products and flows and explanatory notes on the individual country data as well as conversion factors from original units to tonnes of oil equivalent.

Published July 2010 - Price €120

■ Energy Statistics of Non-OECD Countries, 2010 Edition

This publication offers the same in-depth statistical coverage as the homonymous publication covering OECD countries. It includes data in original units for more than 100 individual countries and nine main regions. The consistency of OECD and non-OECD countries' detailed statistics provides an accurate picture of the global energy situation for 2007 and 2008. For a description of the content, please see *Energy Statistics of OECD Countries* above.

Published August 2010 - Price €120

■ **Energy Balances of Non-OECD Countries, 2010 Edition**

A companion volume to the publication *Energy Statistics of Non-OECD Countries*, this publication presents energy balances in million tonnes of oil equivalent and key economic and energy indicators for more than 100 individual countries and nine main regions. It offers the same statistical coverage as the homonymous publication covering OECD countries, and thus provides an accurate picture of the global energy situation for 2007 and 2008. For a description of the content, please see *Energy Balances of OECD Countries* above.

Published August 2010 - Price €120

■ **Electricity Information 2010**

This reference document provides essential statistics on electricity and heat for each OECD member country by bringing together information on production, installed capacity, input energy mix to electricity and heat production, input fuel prices, consumption, end-user electricity prices and electricity trades. The document also presents selected non-OECD country statistics on the main electricity and heat flows. It is an essential document for electricity and heat market and policy analysts.

Published August 2010 - Price €150

■ **Coal Information 2010**

This well-established publication provides detailed information on past and current evolution of the world coal market. It presents country-specific statistics for OECD member countries and selected non-OECD countries on coal production, demand, trade and prices. This publication represents a key reference tool for all those involved in the coal supply or consumption stream, as well as institutions and governments involved in market and policy analysis of the world coal market.

Published August 2010 - Price €165

■ **Natural Gas Information 2010**

A detailed reference work on gas supply and demand, covering not only the OECD countries but also the rest of the world. Contains essential information on LNG and pipeline trade, gas reserves, storage capacity and prices. The main part of the book, however, concentrates on OECD countries, showing a detailed gas supply and demand balance for each individual country and for the three OECD regions: North America, Europe and Asia-Pacific, as well as a breakdown of gas consumption by end-user. Import and export data are reported by source and destination.

Published August 2010 - Price €165

■ **Oil Information 2010**

A comprehensive reference book on current developments in oil supply and demand. The first part of this publication contains key data on world production, trade, prices and consumption of major oil product groups, with time series back to the early 1970s. The second part gives a more detailed and comprehensive picture of oil supply, demand, trade, production and consumption by end-user for each OECD country individually and for the OECD regions. Trade data are reported extensively by origin and destination.

Published August 2010 - Price €165

■ Renewables Information 2010

This reference document brings together in one volume essential statistics on renewables and waste energy sources. It presents a detailed and comprehensive picture of developments for renewable and waste energy sources for each of the OECD member countries, encompassing energy indicators, generating capacity, electricity and heat production from renewable and waste sources, as well as production and consumption of renewable and waste products. It also includes a selection of indicators for non-OECD countries. This report provides a strong foundation for renewables energy policy and market analysis to assess progress towards domestic and international objectives.

Published August 2010 - Price €110

■ CO₂ Emissions from Fuel Combustion, 2010 Edition

In order for nations to tackle the problem of climate change, they need accurate greenhouse gas emissions data. This publication provides a basis for comparative analysis of CO₂ emissions from fossil fuel combustion, a major source of anthropogenic emissions. The data in this book are designed to assist in understanding the evolution of the emissions of CO₂ from 1971 to 2008 for more than 140 countries and regions by sector and by fuel. Emissions were calculated using IEA energy databases and the default methods and emissions factors from the *Revised 1996 IPCC Guidelines for National Greenhouse Gas Inventories*.

Published November 2010 - Price €165

Two Quarterlies

■ Oil, Gas, Coal and Electricity, Quarterly Statistics

This publication provides up-to-date, detailed quarterly statistics on oil, coal, natural gas and electricity for the OECD countries. Oil statistics cover production, trade, refinery intake and output, stock changes and consumption for crude oil, NGL and nine selected oil product groups. Statistics for electricity, natural gas and coal show supply and trade. Import and export data are reported by origin and destination. Moreover, oil as well as hard coal and brown coal production are reported on a worldwide basis.

Published Quarterly - Price €120, annual subscription €380

■ Energy Prices and Taxes

This publication responds to the needs of the energy industry and OECD governments for up-to-date information on prices and taxes in national and international energy markets. It contains prices at all market levels for OECD countries and certain non-OECD countries: import prices, industry prices and consumer prices. The statistics cover the main petroleum products, gas, coal and electricity, giving for imported products an average price both for importing country and country of origin. Every issue includes full notes on sources and methods and a description of price mechanisms in each country.

Published Quarterly - Price €120, annual subscription €380

Electronic Editions

■ CD-ROMs and Online Data Services

To complement its publications, the Energy Statistics Division produces CD-ROMs containing the complete databases which are used for preparing the statistics publications. State-of-the-art software allows you to access and manipulate all these data in a very user-friendly manner and includes graphic facilities. These databases are also available on the internet from our online data service.

Annual CD-ROMS / Online Databases

■ Energy Statistics of OECD Countries, 1960-2009	Price: €550 (single user)
■ Energy Balances of OECD Countries, 1960-2009	Price: €550 (single user)
■ Energy Statistics of Non-OECD Countries, 1971-2008	Price: €550 (single user)
■ Energy Balances of Non-OECD Countries, 1971-2008	Price: €550 (single user)
■ <i>Combined subscription of the above four series</i>	<i>Price: €1 400 (single user)</i>
■ Electricity Information 2010	Price: €550 (single user)
■ Coal Information 2010	Price: €550 (single user)
■ Natural Gas Information 2010	Price: €550 (single user)
■ Oil Information 2010	Price: €550 (single user)
■ Renewables Information 2010	Price: €400 (single user)
■ CO ₂ Emissions from Fuel Combustion, 1971-2008	Price: €550 (single user)

Quarterly CD-ROMs / Online Databases

■ Energy Prices and Taxes	Price: (four quarters) €900 (single user)
---------------------------	---

A description of these services are available on our website: <http://data.iea.org>

Other Online Services

■ The Monthly Oil Data Service

The IEA Monthly Oil Data Service provides the detailed databases of historical and projected information which is used in preparing the IEA's monthly *Oil Market Report* (OMR). The IEA Monthly Oil Data Service comprises three packages available separately or combined as a subscriber service on the Internet. The data are available at the same time as the official release of the Oil Market Report.

The packages include:

■ Supply, Demand, Balances and Stocks	Price: €6 000 (single user)
■ Trade	Price: €2 000 (single user)
■ Field-by-Field Supply	Price: €3 000 (single user)
■ <i>Complete Service</i>	<i>Price: €9 000 (single user)</i>

A description of this service is available on our website: <http://modsinfo.iea.org>

■ The Monthly Gas Data Service

The service provides monthly natural gas data for OECD countries:

- supply balances in terajoules and cubic metres;
- production, trade, stock changes and levels where available, gross inland deliveries, own use and losses;
- highly detailed trade data with about 50 imports origins and exports destinations;
- LNG trade detail available from January 2002.

The databases cover the time period January 1984 to current month with a time lag of two months for the most recent data.

- Monthly Gas Data Service: Natural Gas Balances & Trade
Historical plus 12 monthly updates Price: €800 (single user)

For more information consult: **<http://data.iea.org>**

Moreover, the IEA statistics website contains key energy indicators by country, graphs on the world and OECD's energy situation evolution from 1971 to the most recent year available, as well as selected databases for demonstration.
